#### Framebuffer manipulation

- Control the garbage collector
- Simple regular expressions
- Basic “operating system” services
- System specific functions
- SSL/TLS module
- Mathematical functions
- Simple BTree database
- Zlib decompression
- Time related functions
- Pack and unpack primitive data types
- Frame buffer manipulation

CHAPTER ONE

QUICK REFERENCE FOR THE ESP8266

The Adafruit Feather HUZZAH board (image attribution: Adafruit).

1.1 Installing MicroPython

See the corresponding section of tutorial: *Getting started with MicroPython on the ESP8266*. It also includes a troubleshooting subsection.

1.2 General board control

The MicroPython REPL is on UART0 (GPIO1=TX, GPIO3=RX) at baudrate 115200. Tab-completion is useful to find out what methods an object has. Paste mode (ctrl-E) is useful to paste a large slab of Python code into the REPL.

The `machine` module:

```python
import machine
```
The `esp` module:

```python
import esp

esp.osdebug(None)  # turn off vendor O/S debugging messages
esp.osdebug(0)     # redirect vendor O/S debugging messages to UART(0)
```

### 1.3 Networking

The `network` module:

```python
import network

wlan = network.WLAN(network.STA_IF)  # create station interface
wlan.active(True)                    # activate the interface
wlan.scan()                          # scan for access points
wlan.isconnected()                  # check if the station is connected to an AP
wlan.connect('essid', 'password')   # connect to an AP
wlan.config('mac')                  # get the interface’s MAC address
wlan.ifconfig()                     # get the interface’s IP/netmask/gw/DNS addresses

ap = network.WLAN(network.AP_IF)     # create access-point interface
ap.active(True)                      # activate the interface
ap.config(essid='ESP-AP')            # set the ESSID of the access point
```

A useful function for connecting to your local WiFi network is:

```python
def do_connect():
    import network
    wlan = network.WLAN(network.STA_IF)  # create station interface
    wlan.active(True)                    # activate the interface
    if not wlan.isconnected():
        print('connecting to network...')
        wlan.connect('essid', 'password')
    while not wlan.isconnected():
        pass
    print('network config:', wlan.ifconfig())
```

Once the network is established the `socket` module can be used to create and use TCP/UDP sockets as usual.

### 1.4 Delay and timing

Use the `time` module:

```python
import time

time.sleep(1)  # sleep for 1 second
time.sleep_ms(500)  # sleep for 500 milliseconds
time.sleep_us(10)  # sleep for 10 microseconds
```
start = time.ticks_ms()  # get milliseconds counter
delta = time.ticks_diff(time.ticks_ms(), start)  # compute time difference

1.5 Timers

Virtual (RTOS-based) timers are supported. Use the `machine.Timer` class with timer ID of -1:

```python
from machine import Timer

tim = Timer(-1)
tim.init(period=5000, mode=Timer.ONE_SHOT, callback=lambda t:print(1))
tim.init(period=2000, mode=Timer.PERIODIC, callback=lambda t:print(2))
```

The period is in milliseconds.

1.6 Pins and GPIO

Use the `machine.Pin` class:

```python
from machine import Pin

p0 = Pin(0, Pin.OUT)  # create output pin on GPIO0
p0.on()  # set pin to "on" (high) level
p0.off()  # set pin to "off" (low) level
p0.value(1)  # set pin to on/high

p2 = Pin(2, Pin.IN)  # create input pin on GPIO2
print(p2.value())  # get value, 0 or 1

p4 = Pin(4, Pin.IN, Pin.PULL_UP)  # enable internal pull-up resistor
p5 = Pin(5, Pin.OUT, value=1)  # set pin high on creation
```

Available pins are: 0, 1, 2, 3, 4, 5, 12, 13, 14, 15, 16, which correspond to the actual GPIO pin numbers of ESP8266 chip. Note that many end-user boards use their own adhoc pin numbering (marked e.g. D0, D1, ...). As MicroPython supports different boards and modules, physical pin numbering was chosen as the lowest common denominator. For mapping between board logical pins and physical chip pins, consult your board documentation.

Note that Pin(1) and Pin(3) are REPL UART TX and RX respectively. Also note that Pin(16) is a special pin (used for wakeup from deepsleep mode) and may be not available for use with higher-level classes like Neopixel.

1.7 PWM (pulse width modulation)

PWM can be enabled on all pins except Pin(16). There is a single frequency for all channels, with range between 1 and 1000 (measured in Hz). The duty cycle is between 0 and 1023 inclusive.

Use the `machine.PWM` class:

```python
from machine import Pin, PWM

pwm0 = PWM(Pin(0))  # create PWM object from a pin
pwm0.freq()  # get current frequency
```
1.8 ADC (analog to digital conversion)

ADC is available on a dedicated pin. Note that input voltages on the ADC pin must be between 0v and 1.0v.

Use the `machine.ADC` class:

```python
from machine import ADC
adc = ADC(0)  # create ADC object on ADC pin
adc.read()    # read value, 0-1024
```

1.9 Software SPI bus

There are two SPI drivers. One is implemented in software (bit-banging) and works on all pins, and is accessed via the `machine.SPI` class:

```python
from machine import Pin, SPI

# construct an SPI bus on the given pins
# polarity is the idle state of SCK
# phase=0 means sample on the first edge of SCK, phase=1 means the second
spi = SPI(-1, baudrate=100000, polarity=1, phase=0, sck=Pin(0), mosi=Pin(2),
          miso=Pin(4))
spi.init(baudrate=200000)  # set the baudrate

spi.read(10)             # read 10 bytes on MISO
spi.read(10, 0xff)       # read 10 bytes while outputing 0xff on MOSI
buf = bytearray(50)      # create a buffer
spi.readinto(buf)        # read into the given buffer (reads 50 bytes in this case)
spi.readinto(buf, 0xff)  # read into the given buffer and output 0xff on MOSI
spi.write(b'12345')      # write 5 bytes on MOSI
buf = bytearray(4)       # create a buffer
spi.write_readinto(b'1234', buf)  # write to MOSI and read from MISO into the buffer
spi.write_readinto(buf, buf) # write buf to MOSI and read MISO back into buf
```

1.10 Hardware SPI bus

The hardware SPI is faster (up to 80Mhz), but only works on following pins: `MISO` is GPIO12, `MOSI` is GPIO13, and `SCK` is GPIO14. It has the same methods as the bitbanging SPI class above, except for the pin parameters for the constructor and init (as those are fixed):
from machine import Pin, SPI

hspi = SPI(1, baudrate=80000000, polarity=0, phase=0)

(SPI(0) is used for FlashROM and not available to users.)

### 1.11 I2C bus

The I2C driver is implemented in software and works on all pins, and is accessed via the `machine.I2C` class:

```python
from machine import Pin, I2C

# construct an I2C bus
i2c = I2C(scl=Pin(5), sda=Pin(4), freq=100000)

i2c.readfrom(0x3a, 4)  # read 4 bytes from slave device with address 0x3a
i2c.writeto(0x3a, '12')  # write '12' to slave device with address 0x3a

buf = bytearray(10)  # create a buffer with 10 bytes
i2c.writeto(0x3a, buf)  # write the given buffer to the slave
```

### 1.12 Real time clock (RTC)

See `machine.RTC`

```python
from machine import RTC

rtc = RTC()
rtc.datetime((2017, 8, 23, 1, 12, 48, 0, 0))  # set a specific date and time
rtc.datetime()  # get date and time
```

### 1.13 Deep-sleep mode

Connect GPIO16 to the reset pin (RST on HUZZAH). Then the following code can be used to sleep, wake and check the reset cause:

```python
import machine

# configure RTC.ALARM0 to be able to wake the device
rtc = machine.RTC()
rtc.irq(trigger=machine.ALARM0, wake=machine.DEEPSLEEP)

# check if the device woke from a deep sleep
if machine.reset_cause() == machine.DEEPSLEEP_RESET:
    print('woke from a deep sleep')

# set RTC.ALARM0 to fire after 10 seconds (waking the device)
rtc.alarm(rtc.ALARM0, 10000)

# put the device to sleep
machine.deepsleep()
```

1.11. I2C bus
1.14 OneWire driver

The OneWire driver is implemented in software and works on all pins:

```python
from machine import Pin
import onewire

ow = onewire.OneWire(Pin(12))  # create a OneWire bus on GPIO12
ow.scan()  # return a list of devices on the bus
ow.reset()  # reset the bus
ow.readbyte()  # read a byte
ow.writebyte(0x12)  # write a byte on the bus
ow.write('123')  # write bytes on the bus
ow.select_rom(b'12345678')  # select a specific device by its ROM code
```

There is a specific driver for DS18S20 and DS18B20 devices:

```python
import time, ds18x20
ds = ds18x20.DS18X20(ow)
roms = ds.scan()
ds.convert_temp()
time.sleep_ms(750)
for rom in roms:
    print(ds.read_temp(rom))
```

Be sure to put a 4.7k pull-up resistor on the data line. Note that the `convert_temp()` method must be called each time you want to sample the temperature.

1.15 NeoPixel driver

Use the `neopixel` module:

```python
from machine import Pin
from neopixel import NeoPixel

pin = Pin(0, Pin.OUT)  # set GPIO0 to output to drive NeoPixels
np = NeoPixel(pin, 8)  # create NeoPixel driver on GPIO0 for 8 pixels
np[0] = (255, 255, 255)  # set the first pixel to white
np.write()  # write data to all pixels
r, g, b = np[0]  # get first pixel colour
```

For low-level driving of a NeoPixel:

```python
import esp
esp.neopixel_write(pin, grb_buf, is800khz)
```

1.16 APA102 driver

Use the `apa102` module:
from machine import Pin
from apa102 import APA102

clock = Pin(14, Pin.OUT)  # set GPIO14 to output to drive the clock
data = Pin(13, Pin.OUT)  # set GPIO13 to output to drive the data
apa = APA102(clock, data, 8)  # create APA102 driver on the clock and the data pin for 8 pixels
apa[0] = (255, 255, 255, 31)  # set the first pixel to white with a maximum brightness of 31
apa.write()  # write data to all pixels
r, g, b, brightness = apa[0]  # get first pixel colour

For low-level driving of an APA102:

import esp
esp.apa102_write(clock_pin, data_pin, rgb_buf)

1.17 DHT driver

The DHT driver is implemented in software and works on all pins:

import dht
import machine

d = dht.DHT11(machine.Pin(4))
d.measure()
d.temperature()  # eg. 23 (°C)
d.humidity()  # eg. 41 (% RH)

d = dht.DHT22(machine.Pin(4))
d.measure()
d.temperature()  # eg. 23.6 (°C)
d.humidity()  # eg. 41.3 (% RH)

1.18 WebREPL (web browser interactive prompt)

WebREPL (REPL over WebSockets, accessible via a web browser) is an experimental feature available in ESP8266 port. Download web client from https://github.com/micropython/webrepl (hosted version available at http://micropython.org/webrepl), and configure it by executing:

import webrepl_setup

and following on-screen instructions. After reboot, it will be available for connection. If you disabled automatic start-up on boot, you may run configured daemon on demand using:

import webrepl
webrepl.start()

The supported way to use WebREPL is by connecting to ESP8266 access point, but the daemon is also started on STA interface if it is active, so if your router is set up and works correctly, you may also use WebREPL while connected to your normal Internet access point (use the ESP8266 AP connection method if you face any issues).
Besides terminal/command prompt access, WebREPL also has provision for file transfer (both upload and download). Web client has buttons for the corresponding functions, or you can use command-line client `webrepl_cli.py` from the repository above.

See the MicroPython forum for other community-supported alternatives to transfer files to ESP8266.
GENERAL INFORMATION ABOUT THE ESP8266 PORT

ESP8266 is a popular WiFi-enabled System-on-Chip (SoC) by Espressif Systems.

2.1 Multitude of boards

There is a multitude of modules and boards from different sources which carry the ESP8266 chip. MicroPython tries to provide a generic port which would run on as many boards/modules as possible, but there may be limitations. Adafruit Feather HUZZAH board is taken as a reference board for the port (for example, testing is performed on it). If you have another board, please make sure you have a datasheet, schematics and other reference materials for your board handy to look up various aspects of your board functioning.

To make a generic ESP8266 port and support as many boards as possible, the following design and implementation decision were made:

- GPIO pin numbering is based on ESP8266 chip numbering, not some “logical” numbering of a particular board. Please have the manual/pin diagram of your board at hand to find correspondence between your board pins and actual ESP8266 pins. We also encourage users of various boards to share this mapping via MicroPython forum, with the idea to collect community-maintained reference materials eventually.

- All pins which make sense to support, are supported by MicroPython (for example, pins which are used to connect SPI flash are not exposed, as they’re unlikely useful for anything else, and operating on them will lead to board lock-up). However, any particular board may expose only subset of pins. Consult your board reference manual.

- Some boards may lack external pins/internal connectivity to support ESP8266 deepsleep mode.

2.2 Technical specifications and SoC datasheets

The datasheets and other reference material for ESP8266 chip are available from the vendor site: http://bbs.espressif.com/viewtopic.php?f=67&t=225. They are the primary reference for the chip technical specifications, capabilities, operating modes, internal functioning, etc.

For your convenience, some of technical specifications are provided below:

- Architecture: Xtensa lx106
- CPU frequency: 80MHz overclockable to 160MHz
- Total RAM available: 96KB (part of it reserved for system)
- BootROM: 64KB
- Internal FlashROM: None
• External FlashROM: code and data, via SPI Flash. Normal sizes 512KB-4MB.
• GPIO: 16 + 1 (GPIOs are multiplexed with other functions, including external FlashROM, UART, deep sleep wake-up, etc.)
• UART: One RX/TX UART (no hardware handshaking), one TX-only UART.
• SPI: 2 SPI interfaces (one used for FlashROM).
• I2C: No native external I2C (bitbang implementation available on any pins).
• I2S: 1.
• Programming: using BootROM bootloader from UART. Due to external FlashROM and always-available BootROM bootloader, ESP8266 is not brickable.

2.3 Scarcity of runtime resources

ESP8266 has very modest resources (first of all, RAM memory). So, please avoid allocating too big container objects (lists, dictionaries) and buffers. There is also no full-fledged OS to keep track of resources and automatically clean them up, so that’s the task of a user/user application: please be sure to close open files, sockets, etc. as soon as possible after use.

2.4 Boot process

On boot, MicroPython EPS8266 port executes _boot.py script from internal frozen modules. It mounts filesystem in FlashROM, or if it’s not available, performs first-time setup of the module and creates the filesystem. This part of the boot process is considered fixed, and not available for customization for end users (even if you build from source, please refrain from changes to it; customization of early boot process is available only to advanced users and developers, who can diagnose themselves any issues arising from modifying the standard process).

Once the filesystem is mounted, boot.py is executed from it. The standard version of this file is created during first-time module set up and has commands to start a WebREPL daemon (disabled by default, configurable with webrepl_setup module), etc. This file is customizable by end users (for example, you may want to set some parameters or add other services which should be run on a module start-up). But keep in mind that incorrect modifications to boot.py may still lead to boot loops or lock ups, requiring to reflash a module from scratch. (In particular, it’s recommended that you use either webrepl_setup module or manual editing to configure WebREPL, but not both).

As a final step of boot procedure, main.py is executed from filesystem, if exists. This file is a hook to start up a user application each time on boot (instead of going to REPL). For small test applications, you may name them directly as main.py, and upload to module, but instead it’s recommended to keep your application(s) in separate files, and have just the following in main.py:

```
import my_app
my_app.main()
```

This will allow to keep the structure of your application clear, as well as allow to install multiple applications on a board, and switch among them.
2.5 Known Issues

2.5.1 Real-time clock

RTC in ESP8266 has very bad accuracy, drift may be seconds per minute. As a workaround, to measure short enough intervals you can use utime.time(), etc. functions, and for wall clock time, synchronize from the net using included ntptime.py module.

Due to limitations of the ESP8266 chip the internal real-time clock (RTC) will overflow every 7:45h. If a long-term working RTC time is required then time() or localtime() must be called at least once within 7 hours. MicroPython will then handle the overflow.

2.5.2 Sockets and WiFi buffers overflow

Socket instances remain active until they are explicitly closed. This has two consequences. Firstly they occupy RAM, so an application which opens sockets without closing them may eventually run out of memory. Secondly not properly closed socket can cause the low-level part of the vendor WiFi stack to emit Lmac errors. This occurs if data comes in for a socket and is not processed in a timely manner. This can overflow the WiFi stack input queue and lead to a deadlock. The only recovery is by a hard reset.

The above may also happen after an application terminates and quits to the REPL for any reason including an exception. Subsequent arrival of data provokes the failure with the above error message repeatedly issued. So, sockets should be closed in any case, regardless whether an application terminates successfully or by an exception, for example using try/finally:

```python
sock = socket(...)  
try:  
    # Use sock  
finally:  
    sock.close()
```

2.5.3 SSL/TLS limitations

ESP8266 uses axTLS library, which is one of the smallest TLS libraries with the compatible licensing. However, it also has some known issues/limitations:

1. No support for Diffie-Hellman (DH) key exchange and Elliptic-curve cryptography (ECC). This means it can’t work with sites which force the use of these features (it works ok with classic RSA certificates).
2. Half-duplex communication nature. axTLS uses a single buffer for both sending and receiving, which leads to considerable memory saving and works well with protocols like HTTP. But there may be problems with protocols which don’t follow classic request-response model.

Besides axTLS own limitations, the configuration used for MicroPython is highly optimized for code size, which leads to additional limitations (these may be lifted in the future):

3. Optimized RSA algorithms are not enabled, which may lead to slow SSL handshakes.
4. Stored sessions are not supported (may allow faster repeated connections to the same site in some circumstances).

Besides axTLS specific limitations described above, there’s another generic limitation with usage of TLS on the low-memory devices:

5. The TLS standard specifies the maximum length of the TLS record (unit of TLS communication, the entire record must be buffered before it can be processed) as 16KB. That’s almost half of the available ESP8266
memory, and inside a more or less advanced application would be hard to allocate due to memory fragmentation issues. As a compromise, a smaller buffer is used, with the idea that the most interesting usage for SSL would be accessing various REST APIs, which usually require much smaller messages. The buffers size is on the order of 5KB, and is adjusted from time to time, taking as a reference being able to access https://google.com. The smaller buffer however means that some sites can’t be accessed using it, and it’s not possible to stream large amounts of data.

There are also some not implemented features specifically in MicroPython’s `ussl` module based on axTLS:

6. Certificates are not validated (this may make connections susceptible to man-in-the-middle attacks).
7. There is no support for client certificates (scheduled to be fixed in 1.9.4 release).
This tutorial is intended to get you started using MicroPython on the ESP8266 system-on-a-chip. If it is your first time it is recommended to follow the tutorial through in the order below. Otherwise the sections are mostly self contained, so feel free to skip to those that interest you.

The tutorial does not assume that you know Python, but it also does not attempt to explain any of the details of the Python language. Instead it provides you with commands that are ready to run, and hopes that you will gain a bit of Python knowledge along the way. To learn more about Python itself please refer to https://www.python.org.

3.1 Getting started with MicroPython on the ESP8266

Using MicroPython is a great way to get the most of your ESP8266 board. And vice versa, the ESP8266 chip is a great platform for using MicroPython. This tutorial will guide you through setting up MicroPython, getting a prompt, using WebREPL, connecting to the network and communicating with the Internet, using the hardware peripherals, and controlling some external components.

Let’s get started!

3.1.1 Requirements

The first thing you need is a board with an ESP8266 chip. The MicroPython software supports the ESP8266 chip itself and any board should work. The main characteristic of a board is how much flash it has, how the GPIO pins are connected to the outside world, and whether it includes a built-in USB-serial convertor to make the UART available to your PC.

The minimum requirement for flash size is 1Mbyte. There is also a special build for boards with 512KB, but it is highly limited comparing to the normal build: there is no support for filesystem, and thus features which depend on it won’t work (WebREPL, upip, etc.). As such, 512KB build will be more interesting for users who build from source and fine-tune parameters for their particular application.

Names of pins will be given in this tutorial using the chip names (eg GPIO0) and it should be straightforward to find which pin this corresponds to on your particular board.

3.1.2 Powering the board

If your board has a USB connector on it then most likely it is powered through this when connected to your PC. Otherwise you will need to power it directly. Please refer to the documentation for your board for further details.
3.1.3 Getting the firmware

The first thing you need to do is download the most recent MicroPython firmware .bin file to load onto your ESP8266 device. You can download it from the MicroPython downloads page. From here, you have 3 main choices:

- Stable firmware builds for 1024kb modules and above.
- Daily firmware builds for 1024kb modules and above.
- Daily firmware builds for 512kb modules.

If you are just starting with MicroPython, the best bet is to go for the Stable firmware builds. If you are an advanced, experienced MicroPython ESP8266 user who would like to follow development closely and help with testing new features, there are daily builds (note: you actually may need some development experience, e.g. being ready to follow git history to know what new changes and features were introduced).

Support for 512kb modules is provided on a feature preview basis. For end users, it’s recommended to use modules with flash of 1024kb or more. As such, only daily builds for 512kb modules are provided.

3.1.4 Deploying the firmware

Once you have the MicroPython firmware (compiled code), you need to load it onto your ESP8266 device. There are two main steps to do this: first you need to put your device in boot-loader mode, and second you need to copy across the firmware. The exact procedure for these steps is highly dependent on the particular board and you will need to refer to its documentation for details.

If you have a board that has a USB connector, a USB-serial convertor, and has the DTR and RTS pins wired in a special way then deploying the firmware should be easy as all steps can be done automatically. Boards that have such features include the Adafruit Feather HUZZAH and NodeMCU boards.

For best results it is recommended to first erase the entire flash of your device before putting on new MicroPython firmware.

Currently we only support esptool.py to copy across the firmware. You can find this tool here: https://github.com/espressif/esptool/, or install it using pip:

```
pip install esptool
```

Versions starting with 1.3 support both Python 2.7 and Python 3.4 (or newer). An older version (at least 1.2.1 is needed) works fine but will require Python 2.7.

Any other flashing program should work, so feel free to try them out or refer to the documentation for your board to see its recommendations.

Using esptool.py you can erase the flash with the command:

```
esptool.py --port /dev/ttyUSB0 erase_flash
```

And then deploy the new firmware using:

```
esptool.py --port /dev/ttyUSB0 --baud 460800 write_flash --flash_size=detect 0
            --esp8266-20170108-v1.8.7.bin
```

You might need to change the “port” setting to something else relevant for your PC. You may also need to reduce the baudrate if you get errors when flashing (e.g. down to 115200). The filename of the firmware should also match the file that you have.

For some boards with a particular FlashROM configuration (e.g. some variants of a NodeMCU board) you may need to use the following command to deploy the firmware (note the -fm dio option):
If the above commands run without error then MicroPython should be installed on your board!

### 3.1.5 Serial prompt

Once you have the firmware on the device you can access the REPL (Python prompt) over UART0 (GPIO1=TX, GPIO3=RX), which might be connected to a USB-serial convertor, depending on your board. The baudrate is 115200. The next part of the tutorial will discuss the prompt in more detail.

### 3.1.6 WiFi

After a fresh install and boot the device configures itself as a WiFi access point (AP) that you can connect to. The ESSID is of the form MicroPython-xxxxxx where the x’s are replaced with part of the MAC address of your device (so will be the same everytime, and most likely different for all ESP8266 chips). The password for the WiFi is micropythoN (note the upper-case N). Its IP address will be 192.168.4.1 once you connect to its network. WiFi configuration will be discussed in more detail later in the tutorial.

### 3.1.7 Troubleshooting installation problems

If you experience problems during flashing or with running firmware immediately after it, here are troubleshooting recommendations:

- Be aware of and try to exclude hardware problems. There are 2 common problems: bad power source quality and worn-out/defective FlashROM. Speaking of power source, not just raw amperage is important, but also low ripple and noise/EMI in general. If you experience issues with self-made or wall wart style power supply, try USB power from a computer. Unearthed power supplies are also known to cause problems as they source of increased EMI (electromagnetic interference) - at the very least, and may lead to electrical devices breakdown. So, you are advised to avoid using unearthed power connections when working with ESP8266 and other boards. In regard to FlashROM hardware problems, there are independent (not related to MicroPython in any way) reports (e.g.) that on some ESP8266 modules, FlashROM can be programmed as little as 20 times before programming errors occur. This is much less than 100,000 programming cycles cited for FlashROM chips of a type used with ESP8266 by reputable vendors, which points to either production rejects, or second-hand worn-out flash chips to be used on some (apparently cheap) modules/boards. You may want to use your best judgement about source, price, documentation, warranty, post-sales support for the modules/boards you purchase.

- The flashing instructions above use flashing speed of 460800 baud, which is good compromise between speed and stability. However, depending on your module/board, USB-UART convertor, cables, host OS, etc., the above baud rate may be too high and lead to errors. Try a more common 115200 baud rate instead in such cases.

- If lower baud rate didn’t help, you may want to try older version of esptool.py, which had a different programming algorithm:

  ```
  pip install esptool==1.0.1
  ```

  This version doesn’t support --flash_size=detect option, so you will need to specify FlashROM size explicitly (in megabits). It also requires Python 2.7, so you may need to use pip2 instead of pip in the command above.

- The --flash_size option in the commands above is mandatory. Omitting it will lead to a corrupted firmware.
• To catch incorrect flash content (e.g. from a defective sector on a chip), add `--verify` switch to the commands above.

• Additionally, you can check the firmware integrity from a MicroPython REPL prompt (assuming you were able to flash it and `--verify` option doesn’t report errors):

```python
import esp
esp.check_fw()
```

If the last output value is True, the firmware is OK. Otherwise, it’s corrupted and need to be reflashed correctly.

• If you experience any issues with another flashing application (not esptool.py), try esptool.py, it is a generally accepted flashing application in the ESP8266 community.

• If you still experience problems with even flashing the firmware, please refer to esptool.py project page, [https://github.com/espressif/esptool](https://github.com/espressif/esptool) for additional documentation and bug tracker where you can report problems.

• If you are able to flash firmware, but `--verify` option or `esp.check_fw()` return errors even after multiple retries, you may have a defective FlashROM chip, as explained above.

### 3.2 Getting a MicroPython REPL prompt

REPL stands for Read Evaluate Print Loop, and is the name given to the interactive MicroPython prompt that you can access on the ESP8266. Using the REPL is by far the easiest way to test out your code and run commands.

There are two ways to access the REPL: either via a wired connection through the UART serial port, or via WiFi.

#### 3.2.1 REPL over the serial port

The REPL is always available on the UART0 serial peripheral, which is connected to the pins GPIO1 for TX and GPIO3 for RX. The baudrate of the REPL is 115200. If your board has a USB-serial convertor on it then you should be able to access the REPL directly from your PC. Otherwise you will need to have a way of communicating with the UART.

To access the prompt over USB-serial you need to use a terminal emulator program. On Windows TeraTerm is a good choice, on Mac you can use the built-in screen program, and Linux has picocom and minicom. Of course, there are many other terminal programs that will work, so pick your favourite!

For example, on Linux you can try running:

```
picom /dev/ttyUSB0 -b115200
```

Once you have made the connection over the serial port you can test if it is working by hitting enter a few times. You should see the Python REPL prompt, indicated by `>>>`.

#### 3.2.2 WebREPL - a prompt over WiFi

WebREPL allows you to use the Python prompt over WiFi, connecting through a browser. The latest versions of Firefox and Chrome are supported.

For your convenience, WebREPL client is hosted at [http://micropython.org/webrepl](http://micropython.org/webrepl). Alternatively, you can install it locally from the the GitHub repository [https://github.com/micropython/webrepl](https://github.com/micropython/webrepl).

Before connecting to WebREPL, you should set a password and enable it via a normal serial connection. Initial versions of MicroPython for ESP8266 came with WebREPL automatically enabled on the boot and with the ability to
set a password via WiFi on the first connection, but as WebREPL was becoming more widely known and popular, the initial setup has switched to a wired connection for improved security:

```python
import webrepl_setup
```

Follow the on-screen instructions and prompts. To make any changes active, you will need to reboot your device.

To use WebREPL connect your computer to the ESP8266’s access point (MicroPython-xxxxxx, see the previous section about this). If you have already reconfigured your ESP8266 to connect to a router then you can skip this part.

Once you are on the same network as the ESP8266 you click the “Connect” button (if you are connecting via a router then you may need to change the IP address, by default the IP address is correct when connected to the ESP8266’s access point). If the connection succeeds then you should see a password prompt.

Once you type the password configured at the setup step above, press Enter once more and you should get a prompt looking like `>>>`. You can now start typing Python commands!

### 3.2.3 Using the REPL

Once you have a prompt you can start experimenting! Anything you type at the prompt will be executed after you press the Enter key. MicroPython will run the code that you enter and print the result (if there is one). If there is an error with the text that you enter then an error message is printed.

Try typing the following at the prompt:

```python
>>> print('hello esp8266!')
hello esp8266!
```

Note that you shouldn’t type the `>>>` arrows, they are there to indicate that you should type the text after it at the prompt. And then the line following is what the device should respond with. In the end, once you have entered the text `print("hello esp8266!")` and pressed the Enter key, the output on your screen should look exactly like it does above.

If you already know some python you can now try some basic commands here. For example:

```python
>>> 1 + 2
3
>>> 1 / 2
0.5
>>> 12**34
492223524295202670437113243122008064
```

If your board has an LED attached to GPIO2 (the ESP-12 modules do) then you can turn it on and off using the following code:

```python
>>> import machine
>>> pin = machine.Pin(2, machine.Pin.OUT)
>>> pin.on()
>>> pin.off()
```

Note that `on` method of a Pin might turn the LED off and `off` might turn it on (or vice versa), depending on how the LED is wired on your board. To resolve this, `machine.Signal` class is provided.

### Line editing

You can edit the current line that you are entering using the left and right arrow keys to move the cursor, as well as the delete and backspace keys. Also, pressing Home or ctrl-A moves the cursor to the start of the line, and pressing End
or ctrl-E moves to the end of the line.

**Input history**

The REPL remembers a certain number of previous lines of text that you entered (up to 8 on the ESP8266). To recall previous lines use the up and down arrow keys.

**Tab completion**

Pressing the Tab key will do an auto-completion of the current word that you are entering. This can be very useful to find out functions and methods that a module or object has. Try it out by typing “ma” and then pressing Tab. It should complete to “machine” (assuming you imported machine in the above example). Then type “.” and press Tab again to see a list of all the functions that the machine module has.

**Line continuation and auto-indent**

Certain things that you type will need “continuing”, that is, will need more lines of text to make a proper Python statement. In this case the prompt will change to ... and the cursor will auto-indent the correct amount so you can start typing the next line straight away. Try this by defining the following function:

```python
>>> def toggle(p):
...   p.value(not p.value())
...   ...
...   ...
>>> 
```

In the above, you needed to press the Enter key three times in a row to finish the compound statement (that’s the three lines with just dots on them). The other way to finish a compound statement is to press backspace to get to the start of the line, then press the Enter key. (If you did something wrong and want to escape the continuation mode then press ctrl-C; all lines will be ignored.)

The function you just defined allows you to toggle a pin. The pin object you created earlier should still exist (recreate it if it doesn’t) and you can toggle the LED using:

```python
>>> toggle(pin)
```

Let’s now toggle the LED in a loop (if you don’t have an LED then you can just print some text instead of calling toggle, to see the effect):

```python
>>> import time
>>> while True:
...   toggle(pin)
...   time.sleep_ms(500)
...   ...
...   ...
...   ...
...   
```

This will toggle the LED at 1Hz (half a second on, half a second off). To stop the toggling press ctrl-C, which will raise a KeyboardInterrupt exception and break out of the loop.

The time module provides some useful functions for making delays and doing timing. Use tab completion to find out what they are and play around with them!
Paste mode

Pressing ctrl-E will enter a special paste mode. This allows you to copy and paste a chunk of text into the REPL. If you press ctrl-E you will see the paste-mode prompt:

```
paste mode; Ctrl-C to cancel, Ctrl-D to finish
```  

You can then paste (or type) your text in. Note that none of the special keys or commands work in paste mode (eg Tab or backspace), they are just accepted as-is. Press ctrl-D to finish entering the text and execute it.

Other control commands

There are four other control commands:

- Ctrl-A on a blank line will enter raw REPL mode. This is like a permanent paste mode, except that characters are not echoed back.
- Ctrl-B on a blank line goes to normal REPL mode.
- Ctrl-C cancels any input, or interrupts the currently running code.
- Ctrl-D on a blank line will do a soft reset.

Note that ctrl-A and ctrl-D do not work with WebREPL.

3.3 The internal filesystem

If your device has 1Mbyte or more of storage then it will be set up (upon first boot) to contain a filesystem. This filesystem uses the FAT format and is stored in the flash after the MicroPython firmware.

3.3.1 Creating and reading files

MicroPython on the ESP8266 supports the standard way of accessing files in Python, using the built-in `open()` function.

To create a file try:

```
>>> f = open('data.txt', 'w')
>>> f.write('some data')
9
>>> f.close()
```

The “9” is the number of bytes that were written with the `write()` method. Then you can read back the contents of this new file using:

```
>>> f = open('data.txt')
>>> f.read()
'some data'
>>> f.close()
```

Note that the default mode when opening a file is to open it in read-only mode, and as a text file. Specify `'wb'` as the second argument to `open()` to open for writing in binary mode, and `'rb'` to open for reading in binary mode.
3.3.2 Listing file and more

The os module can be used for further control over the filesystem. First import the module:

```python
>>> import os
```

Then try listing the contents of the filesystem:

```python
>>> os.listdir()
['boot.py', 'port_config.py', 'data.txt']
```

You can make directories:

```python
>>> os.mkdir('dir')
```

And remove entries:

```python
>>> os.remove('data.txt')
```

3.3.3 Start up scripts

There are two files that are treated specially by the ESP8266 when it starts up: boot.py and main.py. The boot.py script is executed first (if it exists) and then once it completes the main.py script is executed. You can create these files yourself and populate them with the code that you want to run when the device starts up.

3.3.4 Accessing the filesystem via WebREPL

You can access the filesystem over WebREPL using the web client in a browser or via the command-line tool. Please refer to Quick Reference and Tutorial sections for more information about WebREPL.

3.4 Network basics

The network module is used to configure the WiFi connection. There are two WiFi interfaces, one for the station (when the ESP8266 connects to a router) and one for the access point (for other devices to connect to the ESP8266). Create instances of these objects using:

```python
>>> import network
>>> sta_if = network.WLAN(network.STA_IF)
>>> ap_if = network.WLAN(network.AP_IF)
```

You can check if the interfaces are active by:

```python
>>> sta_if.active()
False
>>> ap_if.active()
True
```

You can also check the network settings of the interface by:

```python
>>> ap_if.ifconfig()
('192.168.4.1', '255.255.255.0', '192.168.4.1', '8.8.8.8')
```

The returned values are: IP address, netmask, gateway, DNS.
3.4.1 Configuration of the WiFi

Upon a fresh install the ESP8266 is configured in access point mode, so the AP_IF interface is active and the STA_IF interface is inactive. You can configure the module to connect to your own network using the STA_IF interface.

First activate the station interface:

```python
>>> sta_if.active(True)
```

Then connect to your WiFi network:

```python
>>> sta_if.connect('<your ESSID>', '<your password>')
```

To check if the connection is established use:

```python
>>> sta_if.isconnected()
```

Once established you can check the IP address:

```python
>>> sta_if.ifconfig()
('192.168.0.2', '255.255.255.0', '192.168.0.1', '8.8.8.8')
```

You can then disable the access-point interface if you no longer need it:

```python
>>> ap_if.active(False)
```

Here is a function you can run (or put in your boot.py file) to automatically connect to your WiFi network:

```python
def do_connect():
    import network
    sta_if = network.WLAN(network.STA_IF)
    if not sta_if.isconnected():
        print('connecting to network...')
        sta_if.active(True)
        sta_if.connect('<essid>', '<password>')
    while not sta_if.isconnected():
        pass
    print('network config:', sta_if.ifconfig())
```

3.4.2 Sockets

Once the WiFi is set up the way to access the network is by using sockets. A socket represents an endpoint on a network device, and when two sockets are connected together communication can proceed. Internet protocols are built on top of sockets, such as email (SMTP), the web (HTTP), telnet, ssh, among many others. Each of these protocols is assigned a specific port, which is just an integer. Given an IP address and a port number you can connect to a remote device and start talking with it.

The next part of the tutorial discusses how to use sockets to do some common and useful network tasks.

3.5 Network - TCP sockets

The building block of most of the internet is the TCP socket. These sockets provide a reliable stream of bytes between the connected network devices. This part of the tutorial will show how to use TCP sockets in a few different cases.
3.5.1 Star Wars Asciimation

The simplest thing to do is to download data from the internet. In this case we will use the Star Wars Asciimation service provided by the blinkenlights.nl website. It uses the telnet protocol on port 23 to stream data to anyone that connects. It’s very simple to use because it doesn’t require you to authenticate (give a username or password), you can just start downloading data straight away.

The first thing to do is make sure we have the socket module available:

```python
>>> import socket
```

Then get the IP address of the server:

```python
>>> addr_info = socket.getaddrinfo("towel.blinkenlights.nl", 23)
```

The `getaddrinfo` function actually returns a list of addresses, and each address has more information than we need. We want to get just the first valid address, and then just the IP address and port of the server. To do this use:

```python
>>> addr = addr_info[0][-1]
```

If you type `addr_info` and `addr` at the prompt you will see exactly what information they hold.

Using the IP address we can make a socket and connect to the server:

```python
>>> s = socket.socket()
>>> s.connect(addr)
```

Now that we are connected we can download and display the data:

```python
>>> while True:
...    data = s.recv(500)
...    print(str(data, 'utf8'), end='')
...
```

When this loop executes it should start showing the animation (use ctrl-C to interrupt it).

You should also be able to run this same code on your PC using normal Python if you want to try it out there.

3.5.2 HTTP GET request

The next example shows how to download a webpage. HTTP uses port 80 and you first need to send a “GET” request before you can download anything. As part of the request you need to specify the page to retrieve.

Let’s define a function that can download and print a URL:

```python
def http_get(url):
    _, __, host, path = url.split('/', 3)
    addr = socket.getaddrinfo(host, 80)[0][-1]
    s = socket.socket()
    s.connect(addr)
    s.send(bytes('GET /%s HTTP/1.0\r\n\r
Host: %s\r\n\n' % (path, host), 'utf8'))
    while True:
        data = s.recv(100)
        if data:
            print(str(data, 'utf8'), end='')
        else:
            break
    s.close()
```
Make sure that you import the socket module before running this function. Then you can try:

```python
>>> http_get('http://micropython.org/ks/test.html')
```

This should retrieve the webpage and print the HTML to the console.

### 3.5.3 Simple HTTP server

The following code creates an simple HTTP server which serves a single webpage that contains a table with the state of all the GPIO pins:

```python
import machine
pins = [machine.Pin(i, machine.Pin.IN) for i in (0, 2, 4, 5, 12, 13, 14, 15)]
html = '''<!DOCTYPE html>
<html>
<head> <title>ESP8266 Pins</title> </head>
<body> <h1>ESP8266 Pins</h1>
<table border="1"> <tr><th>Pin</th><th>Value</th></tr>
%s
</table>
</body>
</html>
'''

import socket
addr = socket.getaddrinfo('0.0.0.0', 80)[0][-1]
s = socket.socket()
s.bind(addr)
s.listen(1)
print('listening on', addr)
while True:
    cl, addr = s.accept()
    print('client connected from', addr)
    cl_file = cl.makefile('rwb', 0)
    while True:
        line = cl_file.readline()
        if not line or line == b'
':
            break
    rows = ['<tr><td>%s</td><td>%d</td></tr>' % (str(p), p.value()) for p in pins]
    response = html % '
'.join(rows)
    cl.send(response)
    cl.close()
```

### 3.6 GPIO Pins

The way to connect your board to the external world, and control other components, is through the GPIO pins. Not all pins are available to use, in most cases only pins 0, 2, 4, 5, 12, 13, 14, 15, and 16 can be used.

The pins are available in the machine module, so make sure you import that first. Then you can create a pin using:

```python
>>> pin = machine.Pin(0)
```
Here, the “0” is the pin that you want to access. Usually you want to configure the pin to be input or output, and you do this when constructing it. To make an input pin use:

```python
>>> pin = machine.Pin(0, machine.Pin.IN, machine.Pin.PULL_UP)
```

You can either use PULL_UP or None for the input pull-mode. If it’s not specified then it defaults to None, which is no pull resistor. GPIO16 has no pull-up mode. You can read the value on the pin using:

```python
>>> pin.value()
0
```

The pin on your board may return 0 or 1 here, depending on what it’s connected to. To make an output pin use:

```python
>>> pin = machine.Pin(0, machine.Pin.OUT)
```

Then set its value using:

```python
>>> pin.value(0)
>>> pin.value(1)
```

Or:

```python
>>> pin.off()
>>> pin.on()
```

### 3.6.1 External interrupts

All pins except number 16 can be configured to trigger a hard interrupt if their input changes. You can set code (a callback function) to be executed on the trigger.

Let’s first define a callback function, which must take a single argument, being the pin that triggered the function. We will make the function just print the pin:

```python
>>> def callback(p):
...     print('pin change', p)
```

Next we will create two pins and configure them as inputs:

```python
>>> from machine import Pin
>>> p0 = Pin(0, Pin.IN)
>>> p2 = Pin(2, Pin.IN)
```

And finally we need to tell the pins when to trigger, and the function to call when they detect an event:

```python
>>> p0.irq(trigger=Pin.IRQ_FALLING, handler=callback)
>>> p2.irq(trigger=Pin.IRQ_RISING | Pin.IRQ_FALLING, handler=callback)
```

We set pin 0 to trigger only on a falling edge of the input (when it goes from high to low), and set pin 2 to trigger on both a rising and falling edge. After entering this code you can apply high and low voltages to pins 0 and 2 to see the interrupt being executed.

A hard interrupt will trigger as soon as the event occurs and will interrupt any running code, including Python code. As such your callback functions are limited in what they can do (they cannot allocate memory, for example) and should be as short and simple as possible.
3.7 Pulse Width Modulation

Pulse width modulation (PWM) is a way to get an artificial analog output on a digital pin. It achieves this by rapidly toggling the pin from low to high. There are two parameters associated with this: the frequency of the toggling, and the duty cycle. The duty cycle is defined to be how long the pin is high compared with the length of a single period (low plus high time). Maximum duty cycle is when the pin is high all of the time, and minimum is when it is low all of the time.

On the ESP8266 the pins 0, 2, 4, 5, 12, 13, 14 and 15 all support PWM. The limitation is that they must all be at the same frequency, and the frequency must be between 1Hz and 1kHz.

To use PWM on a pin you must first create the pin object, for example:

```python
>>> import machine

>>> p12 = machine.Pin(12)
```

Then create the PWM object using:

```python
>>> pwm12 = machine.PWM(p12)
```

You can set the frequency and duty cycle using:

```python
>>> pwm12.freq(500)

>>> pwm12.duty(512)
```

Note that the duty cycle is between 0 (all off) and 1023 (all on), with 512 being a 50% duty. Values beyond this min/max will be clipped. If you print the PWM object then it will tell you its current configuration:

```python
>>> pwm12
PWM(12, freq=500, duty=512)
```

You can also call the `freq()` and `duty()` methods with no arguments to get their current values.

The pin will continue to be in PWM mode until you deinitialise it using:

```python
>>> pwm12.deinit()
```

3.7.1 Fading an LED

Let’s use the PWM feature to fade an LED. Assuming your board has an LED connected to pin 2 (ESP-12 modules do) we can create an LED-PWM object using:

```python
>>> led = machine.PWM(machine.Pin(2), freq=1000)
```

Notice that we can set the frequency in the PWM constructor.

For the next part we will use timing and some math, so import these modules:

```python
>>> import time, math
```

Then create a function to pulse the LED:

```python
>>> def pulse(l, t):
...    for i in range(20):
...        l.duty(int(math.sin(i / 10 * math.pi) * 500 + 500))
...        time.sleep_ms(t)
```

3.7. Pulse Width Modulation
You can try this function out using:

```python
>>> pulse(led, 50)
```

For a nice effect you can pulse many times in a row:

```python
>>> for i in range(10):
...    pulse(led, 20)
```

Remember you can use ctrl-C to interrupt the code.

### 3.7.2 Control a hobby servo

Hobby servo motors can be controlled using PWM. They require a frequency of 50Hz and then a duty between about 40 and 115, with 77 being the centre value. If you connect a servo to the power and ground pins, and then the signal line to pin 12 (other pins will work just as well), you can control the motor using:

```python
>>> servo = machine.PWM(machine.Pin(12), freq=50)
>>> servo.duty(40)
>>> servo.duty(115)
>>> servo.duty(77)
```

### 3.8 Analog to Digital Conversion

The ESP8266 has a single pin (separate to the GPIO pins) which can be used to read analog voltages and convert them to a digital value. You can construct such an ADC pin object using:

```python
>>> import machine
>>> adc = machine.ADC(0)
```

Then read its value with:

```python
>>> adc.read()
58
```

The values returned from the `read()` function are between 0 (for 0.0 volts) and 1024 (for 1.0 volts). Please note that this input can only tolerate a maximum of 1.0 volts and you must use a voltage divider circuit to measure larger voltages.

### 3.9 Power control

The ESP8266 provides the ability to change the CPU frequency on the fly, and enter a deep-sleep state. Both can be used to manage power consumption.

#### 3.9.1 Changing the CPU frequency

The machine module has a function to get and set the CPU frequency. To get the current frequency use:

```python
>>> import machine
>>> machine.freq()
80000000
```
By default the CPU runs at 80MHz. It can be changed to 160MHz if you need more processing power, at the expense of current consumption:

```
>>> machine.freq(160000000)
>>> machine.freq()
160000000
```

You can change to the higher frequency just while your code does the heavy processing and then change back when it’s finished.

### 3.9.2 Deep-sleep mode

The deep-sleep mode will shut down the ESP8266 and all its peripherals, including the WiFi (but not including the real-time-clock, which is used to wake the chip). This drastically reduces current consumption and is a good way to make devices that can run for a while on a battery.

To be able to use the deep-sleep feature you must connect GPIO16 to the reset pin (RST on the Adafruit Feather HUZZAH board). Then the following code can be used to sleep and wake the device:

```python
import machine

# configure RTC.ALARM0 to be able to wake the device
rtc = machine.RTC()
rtc.irq(trigger=rtc.ALARM0, wake=machine.DEEPSLEEP)

# set RTC.ALARM0 to fire after 10 seconds (waking the device)
rtc.alarm(rtc.ALARM0, 10000)

# put the device to sleep
machine.deepsleep()
```

Note that when the chip wakes from a deep-sleep it is completely reset, including all of the memory. The boot scripts will run as usual and you can put code in them to check the reset cause to perhaps do something different if the device just woke from a deep-sleep. For example, to print the reset cause you can use:

```python
if machine.reset_cause() == machine.DEEPSLEEP_RESET:
    print('woke from a deep sleep')
else:
    print('power on or hard reset')
```

### 3.10 Controlling 1-wire devices

The 1-wire bus is a serial bus that uses just a single wire for communication (in addition to wires for ground and power). The DS18B20 temperature sensor is a very popular 1-wire device, and here we show how to use the onewire module to read from such a device.

For the following code to work you need to have at least one DS18S20 or DS18B20 temperature sensor with its data line connected to GPIO12. You must also power the sensors and connect a 4.7k Ohm resistor between the data pin and the power pin.

```python
import time
import machine
import onewire, ds18x20
```
# the device is on GPIO12
dat = machine.Pin(12)

# create the onewire object
ds = ds18x20.DS18X20(onewire.OneWire(dat))

# scan for devices on the bus
roms = ds.scan()
print('found devices:', roms)

# loop 10 times and print all temperatures
for i in range(10):
    print('temperatures:', end=' ')
    ds.convert_temp()
    time.sleep_ms(750)
    for rom in roms:
        print(ds.read_temp(rom), end=' ')
    print()

Note that you must execute the `convert_temp()` function to initiate a temperature reading, then wait at least 750ms before reading the value.

## 3.11 Controlling NeoPixels

NeoPixels, also known as WS2812 LEDs, are full-colour LEDs that are connected in serial, are individually addressable, and can have their red, green and blue components set between 0 and 255. They require precise timing to control them and there is a special neopixel module to do just this.

To create a NeoPixel object do the following:

```python
>>> import machine, neopixel
>>> np = neopixel.NeoPixel(machine.Pin(4), 8)
```

This configures a NeoPixel strip on GPIO4 with 8 pixels. You can adjust the “4” (pin number) and the “8” (number of pixel) to suit your set up.

To set the colour of pixels use:

```python
>>> np[0] = (255, 0, 0)  # set to red, full brightness
>>> np[1] = (0, 128, 0)  # set to green, half brightness
>>> np[2] = (0, 0, 64)   # set to blue, quarter brightness
```

For LEDs with more than 3 colours, such as RGBW pixels or RGBY pixels, the NeoPixel class takes a `bpp` parameter. To setup a NeoPixel object for an RGBW Pixel, do the following:

```python
>>> import machine, neopixel
>>> np = neopixel.NeoPixel(machine.Pin(4), 8, bpp=4)
```

In a 4-bpp mode, remember to use 4-tuples instead of 3-tuples to set the colour. For example to set the first three pixels use:

```python
>>> np[0] = (255, 0, 0, 128)  # Orange in an RGBY Setup
>>> np[1] = (0, 255, 0, 128)  # Yellow-green in an RGBY Setup
>>> np[2] = (0, 0, 255, 128)  # Green-blue in an RGBY Setup
```

Then use the `write()` method to output the colours to the LEDs:
The following demo function makes a fancy show on the LEDs:

```python
import time
def demo(np):
    n = np.n

    # cycle
    for i in range(4 * n):
        for j in range(n):
            np[j] = (0, 0, 0)
            np[i % n] = (255, 255, 255)
            np.write()
            time.sleep_ms(25)

    # bounce
    for i in range(4 * n):
        for j in range(n):
            np[j] = (0, 0, 128)
            if (i // n) % 2 == 0:
                np[i % n] = (0, 0, 0)
            else:
                np[n - 1 - (i % n)] = (0, 0, 0)
            np.write()
            time.sleep_ms(60)

    # fade in/out
    for i in range(0, 4 * 256, 8):
        for j in range(n):
            if (i // 256) % 2 == 0:
                val = i & 0xff
            else:
                val = 255 - (i & 0xff)
            np[j] = (val, 0, 0)
        np.write()

    # clear
    for i in range(n):
        np[i] = (0, 0, 0)
        np.write()
```

Execute it using:

```python
>>> demo(np)
```

### 3.12 Temperature and Humidity

DHT (Digital Humidity & Temperature) sensors are low cost digital sensors with capacitive humidity sensors and thermistors to measure the surrounding air. They feature a chip that handles analog to digital conversion and provide a 1-wire interface. Newer sensors additionally provide an I2C interface.

The DHT11 (blue) and DHT22 (white) sensors provide the same 1-wire interface, however, the DHT22 requires a separate object as it has more complex calculation. DHT22 have 1 decimal place resolution for both humidity and temperature readings. DHT11 have whole number for both.
A custom 1-wire protocol, which is different to Dallas 1-wire, is used to get the measurements from the sensor. The
payload consists of a humidity value, a temperature value and a checksum.

To use the 1-wire interface, construct the objects referring to their data pin:

```python
>>> import dht
>>> import machine
>>> d = dht.DHT11(machine.Pin(4))
>>> import dht
>>> import machine
>>> d = dht.DHT22(machine.Pin(4))
```

Then measure and read their values with:

```python
>>> d.measure()
>>> d.temperature()
>>> d.humidity()
```

Values returned from `temperature()` are in degrees Celsius and values returned from `humidity()` are a per-
centage of relative humidity.

The DHT11 can be called no more than once per second and the DHT22 once every two seconds for most accurate
results. Sensor accuracy will degrade over time. Each sensor supports a different operating range. Refer to the product
datasheets for specifics.

In 1-wire mode, only three of the four pins are used and in I2C mode, all four pins are used. Older sensors may still
have 4 pins even though they do not support I2C. The 3rd pin is simply not connected.

Pin configurations:

Sensor without I2C in 1-wire mode (eg. DHT11, DHT22, AM2301, AM2302):

1=VDD, 2=Data, 3=NC, 4=GND

Sensor with I2C in 1-wire mode (eg. DHT12, AM2320, AM2321, AM2322):

1=VDD, 2=Data, 3=GND, 4=GND

Sensor with I2C in I2C mode (eg. DHT12, AM2320, AM2321, AM2322):

1=VDD, 2=SDA, 3=GND, 4=SCL

You should use pull-up resistors for the Data, SDA and SCL pins.

To make newer I2C sensors work in backwards compatible 1-wire mode, you must connect both pins 3 and 4 to GND.
This disables the I2C interface.

DHT22 sensors are now sold under the name AM2302 and are otherwise identical.

### 3.13 Next steps

That brings us to the end of the tutorial! Hopefully by now you have a good feel for the capabilities of MicroPython
on the ESP8266 and understand how to control both the WiFi and IO aspects of the chip.

There are many features that were not covered in this tutorial. The best way to learn about them is to read the full
documentation of the modules, and to experiment!

Good luck creating your Internet of Things devices!
Warning: Important summary of this section

- MicroPython implements a subset of Python functionality for each module.
- To ease extensibility, MicroPython versions of standard Python modules usually have \textit{u} (“micro”) prefix.
- Any particular MicroPython variant or port may miss any feature/function described in this general documentation (due to resource constraints or other limitations).

This chapter describes modules (function and class libraries) which are built into MicroPython. There are a few categories of such modules:

- Modules which implement a subset of standard Python functionality and are not intended to be extended by the user.
- Modules which implement a subset of Python functionality, with a provision for extension by the user (via Python code).
- Modules which implement MicroPython extensions to the Python standard libraries.
- Modules specific to a particular MicroPython port and thus not portable.

Note about the availability of the modules and their contents: This documentation in general aspires to describe all modules and functions/classes which are implemented in MicroPython project. However, MicroPython is highly configurable, and each port to a particular board/embedded system makes available only a subset of MicroPython libraries. For officially supported ports, there is an effort to either filter out non-applicable items, or mark individual descriptions with “Availability:” clauses describing which ports provide a given feature.

With that in mind, please still be warned that some functions/classes in a module (or even the entire module) described in this documentation may be unavailable in a particular build of MicroPython on a particular system. The best place to find general information of the availability/non-availability of a particular feature is the “General Information” section which contains information pertaining to a specific MicroPython port.

Beyond the built-in libraries described in this documentation, many more modules from the Python standard library, as well as further MicroPython extensions to it, can be found in \texttt{micropython-lib}.

4.1 Python standard libraries and micro-libraries

The following standard Python libraries have been “micro-ified” to fit in with the philosophy of MicroPython. They provide the core functionality of that module and are intended to be a drop-in replacement for the standard Python library. Some modules below use a standard Python name, but prefixed with “\texttt{u}”, e.g. \texttt{ujson} instead of \texttt{json}. This is to signify that such a module is micro-library, i.e. implements only a subset of CPython module functionality.
By naming them differently, a user has a choice to write a Python-level module to extend functionality for better compatibility with CPython (indeed, this is what done by the `micropython-lib` project mentioned above).

On some embedded platforms, where it may be cumbersome to add Python-level wrapper modules to achieve naming compatibility with CPython, micro-modules are available both by their u-name, and also by their non-u-name. The non-u-name can be overridden by a file of that name in your library path (`sys.path`). For example, `import json` will first search for a file `json.py` (or package directory `json`) and load that module if it is found. If nothing is found, it will fallback to loading the built-in `ujson` module.

### 4.1.1 Builtin functions and exceptions

All builtin functions and exceptions are described here. They are also available via `builtins` module.

#### Functions and types

- `abs()`
- `all()`
- `any()`
- `bin()`
- `class bool`
- `class bytearray`
- `class bytes`
  
  See CPython documentation: `bytes`.
- `callable()`
- `chr()`
- `classmethod()`
- `compile()`
- `class complex`
- `delattr(obj, name)`
  
  The argument `name` should be a string, and this function deletes the named attribute from the object given by `obj`.
- `class dict`
- `dir()`
- `divmod()`
- `enumerate()`
- `eval()`
- `exec()`
- `filter()`
- `class float`
- `class frozenset`
- `getattr()`
- `getattr()`
globals()
hasattr()
hash()
hex()
id()
input()
class int

classmethod from_bytes(bytes, byteorder)
    In MicroPython, byteorder parameter must be positional (this is compatible with CPython).

to_bytes(size, byteorder)
    In MicroPython, byteorder parameter must be positional (this is compatible with CPython).

isinstance()
issubclass()
iter()
len()
class list
locals()
map()
max()
class memoryview
min()
next()
class object
oct()
open()
ord()
pow()
print()
property()
range()
repr()
reversed()
round()
class set
setattr()
class slice
    The `slice` builtin is the type that slice objects have.

sorted()
staticmethod()
class str
    sum()
    super()
class tuple
    type()
    zip()

Exceptions

exception AssertionError
exception AttributeError
exception Exception
exception ImportError
exception IndexError
exception KeyboardInterrupt
exception KeyError
exception MemoryError
exception NameError
exception NotImplementedError
exception OSError
    See CPython documentation: `OSError`. MicroPython doesn’t implement `errno` attribute, instead use the standard way to access exception arguments: `exc.args[0]`.
exception RuntimeError
exception StopIteration
exception SyntaxError
exception SystemExit
    See CPython documentation: `SystemExit`.
exception TypeError
    See CPython documentation: `TypeError`.
exception ValueError
exception ZeroDivisionError
4.1.2 array – arrays of numeric data

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: array.

Supported format codes: b, B, h, H, i, I, l, L, q, Q, f, d (the latter 2 depending on the floating-point support).

Classes

class array.array(typecode[, iterable])
Create array with elements of given type. Initial contents of the array are given by iterable. If it is not provided, an empty array is created.

append(val)
Append new element val to the end of array, growing it.

extend(iterable)
Append new elements as contained in iterable to the end of array, growing it.

4.1.3 gc – control the garbage collector

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: gc.

Functions

gc.enable()
Enable automatic garbage collection.

gc.disable()
Disable automatic garbage collection. Heap memory can still be allocated, and garbage collection can still be initiated manually using gc.collect().

gc.collect()
Run a garbage collection.

gc.mem_alloc()
Return the number of bytes of heap RAM that are allocated.

Difference to CPython
This function is MicroPython extension.

--

gc.mem_free()
Return the number of bytes of available heap RAM, or -1 if this amount is not known.

Difference to CPython
This function is MicroPython extension.

--

gc.threshold([amount])
Set or query the additional GC allocation threshold. Normally, a collection is triggered only when a new allocation cannot be satisfied, i.e. on an out-of-memory (OOM) condition. If this function is called, in addition to
OOM, a collection will be triggered each time after \textit{amount} bytes have been allocated (in total, since the previous time such an amount of bytes have been allocated). \textit{amount} is usually specified as less than the full heap size, with the intention to trigger a collection earlier than when the heap becomes exhausted, and in the hope that an early collection will prevent excessive memory fragmentation. This is a heuristic measure, the effect of which will vary from application to application, as well as the optimal value of the \textit{amount} parameter.

Calling the function without argument will return the current value of the threshold. A value of -1 means a disabled allocation threshold.

\textbf{Difference to CPython}

This function is a MicroPython extension. CPython has a similar function \texttt{-set\_threshold()}, but due to different GC implementations, its signature and semantics are different.

\section*{4.1.4 \texttt{math} – mathematical functions}

\textit{This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: \texttt{math}.}

The \texttt{math} module provides some basic mathematical functions for working with floating-point numbers.

\textit{Note:} On the pyboard, floating-point numbers have 32-bit precision.

\textbf{Availability:} not available on WiPy. Floating point support required for this module.

\textbf{Functions}

\begin{verbatim}
math.acos(x)
    Return the inverse cosine of x.

math.acosh(x)
    Return the inverse hyperbolic cosine of x.

math.asin(x)
    Return the inverse sine of x.

math.asinh(x)
    Return the inverse hyperbolic sine of x.

math.atan(x)
    Return the inverse tangent of x.

math.atan2(y,x)
    Return the principal value of the inverse tangent of y/x.

math.atanh(x)
    Return the inverse hyperbolic tangent of x.

math.ceil(x)
    Return an integer, being x rounded towards positive infinity.

math.copysign(x, y)
    Return x with the sign of y.

math.cos(x)
    Return the cosine of x.
\end{verbatim}
math.cosh(x)
    Return the hyperbolic cosine of x.

math.degrees(x)
    Return radians x converted to degrees.

math.erf(x)
    Return the error function of x.

math.erfc(x)
    Return the complementary error function of x.

math.exp(x)
    Return the exponential of x.

math.expm1(x)
    Return exp(x) - 1.

math.fabs(x)
    Return the absolute value of x.

math.floor(x)
    Return an integer, being x rounded towards negative infinity.

math.fmod(x, y)
    Return the remainder of x/y.

math.frexp(x)
    Decomposes a floating-point number into its mantissa and exponent. The returned value is the tuple (m, e) such that x == m * 2**e exactly. If x == 0 then the function returns (0.0, 0), otherwise the relation 0.5 <= abs(m) < 1 holds.

math.gamma(x)
    Return the gamma function of x.

math.isfinite(x)
    Return True if x is finite.

math.isinf(x)
    Return True if x is infinite.

math.isnan(x)
    Return True if x is not-a-number

math.ldexp(x, exp)
    Return x * (2**exp).

math.lgamma(x)
    Return the natural logarithm of the gamma function of x.

math.log(x)
    Return the natural logarithm of x.

math.log10(x)
    Return the base-10 logarithm of x.

math.log2(x)
    Return the base-2 logarithm of x.

math.modf(x)
    Return a tuple of two floats, being the fractional and integral parts of x. Both return values have the same sign as x.
math.pow(x, y)
  Returns x to the power of y.

math.radians(x)
  Return degrees x converted to radians.

math.sin(x)
  Return the sine of x.

math.sinh(x)
  Return the hyperbolic sine of x.

math.sqrt(x)
  Return the square root of x.

math.tan(x)
  Return the tangent of x.

math.tanh(x)
  Return the hyperbolic tangent of x.

math.trunc(x)
  Return an integer, being x rounded towards 0.

Constants

math.e
  base of the natural logarithm

math.pi
  the ratio of a circle’s circumference to its diameter

4.1.5 sys – system specific functions

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: sys.

Functions

sys.exit(retval=0)
  Terminate current program with a given exit code. Underlyingly, this function raise as SystemExit exception. If an argument is given, its value given as an argument to SystemExit.

sys.print_exception(exc, file=sys.stdout)
  Print exception with a traceback to a file-like object file (or sys.stdout by default).

Difference to CPython

This is simplified version of a function which appears in the traceback module in CPython. Unlike traceback.print_exception(), this function takes just exception value instead of exception type, exception value, and traceback object; file argument should be positional; further arguments are not supported. CPython-compatible traceback module can be found in micropython-lib.
Constants

**sys.argv**
A mutable list of arguments the current program was started with.

**sys.byteorder**
The byte order of the system ("little" or "big").

**sys.implementation**
Object with information about the current Python implementation. For MicroPython, it has following attributes:

- `name` - string “micropython”
- `version` - tuple (major, minor, micro), e.g. (1, 7, 0)

This object is the recommended way to distinguish MicroPython from other Python implementations (note that it still may not exist in the very minimal ports).

**Difference to CPython**

CPython mandates more attributes for this object, but the actual useful bare minimum is implemented in MicroPython.

**sys.maxsize**
Maximum value which a native integer type can hold on the current platform, or maximum value representable by MicroPython integer type, if it’s smaller than platform max value (that is the case for MicroPython ports without long int support).

This attribute is useful for detecting “bitness” of a platform (32-bit vs 64-bit, etc.). It’s recommended to not compare this attribute to some value directly, but instead count number of bits in it:

```python
bits = 0
v = sys.maxsize
while v:
    bits += 1
    v >>= 1
if bits > 32:
    # 64-bit (or more) platform
    ...
else:
    # 32-bit (or less) platform
    # Note that on 32-bit platform, value of bits may be less than 32
    # (e.g. 31) due to peculiarities described above, so use ”> 16”,
    # ”> 32”, ”> 64” style of comparisons.
```

**sys.modules**
Dictionary of loaded modules. On some ports, it may not include builtin modules.

**sys.path**
A mutable list of directories to search for imported modules.

**sys.platform**
The platform that MicroPython is running on. For OS/RTOS ports, this is usually an identifier of the OS, e.g. "linux". For baremetal ports it is an identifier of a board, e.g. "pyboard" for the original MicroPython reference board. It thus can be used to distinguish one board from another. If you need to check whether your program runs on MicroPython (vs other Python implementation), use `sys.implementation` instead.

**sys.stderr**
Standard error stream.

4.1. Python standard libraries and micro-libraries
MicroPython Documentation, Release 1.9.4

sys.stdin
Standard input stream.

sys.stdout
Standard output stream.

sys.version
Python language version that this implementation conforms to, as a string.

sys.version_info
Python language version that this implementation conforms to, as a tuple of ints.

4.1.6 ubinascii – binary/ASCII conversions

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: binascii.

This module implements conversions between binary data and various encodings of it in ASCII form (in both directions).

Functions

ubinascii.hexlify(data[, sep])
Convert binary data to hexadecimal representation. Returns bytes string.

---

Difference to CPython
If additional argument, sep is supplied, it is used as a separator between hexadecimal values.

ubinascii.unhexlify(data)
Convert hexadecimal data to binary representation. Returns bytes string. (i.e. inverse of hexlify)

ubinascii.a2b_base64(data)
Decode base64-encoded data, ignoring invalid characters in the input. Conforms to RFC 2045 s.6.8. Returns a bytes object.

ubinascii.b2a_base64(data)
Encode binary data in base64 format, as in RFC 3548. Returns the encoded data followed by a newline character, as a bytes object.

4.1.7 ucollections – collection and container types

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: collections.

This module implements advanced collection and container types to hold/accumulate various objects.

Classes

ucollections.namedtuple(name, fields)
This is factory function to create a new namedtuple type with a specific name and set of fields. A namedtuple is a subclass of tuple which allows to access its fields not just by numeric index, but also with an attribute access syntax using symbolic field names. Fields is a sequence of strings specifying field names. For compatibility
with CPython it can also be a string with space-separated field named (but this is less efficient). Example of use:

```python
from ucollections import namedtuple

MyTuple = namedtuple("MyTuple", ("id", "name"))
t1 = MyTuple(1, "foo")
t2 = MyTuple(2, "bar")
print(t1.name)
assert t2.name == t2[1]
```

`ucollections.OrderedDict(...)`
dict type subclass which remembers and preserves the order of keys added. When ordered dict is iterated over, keys/items are returned in the order they were added:

```python
from ucollections import OrderedDict

# To make benefit of ordered keys, OrderedDict should be initialized
# from sequence of (key, value) pairs.
d = OrderedDict([("z", 1), ("a", 2)])
# More items can be added as usual
d["w"] = 5
d["b"] = 3
for k, v in d.items():
    print(k, v)
```

Output:

```
z 1
a 2
w 5
b 3
```

### 4.1.8 uerrno – system error codes

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: `errno`.

This module provides access to symbolic error codes for `OSError` exception. A particular inventory of codes depends on MicroPython port.

#### Constants

**EEXIST, EAGAIN, etc.**

Error codes, based on ANSI C/POSIX standard. All error codes start with “E”. As mentioned above, inventory of the codes depends on MicroPython port. Errors are usually accessible as `exc.args[0]` where `exc` is an instance of `OSError`. Usage example:

```python
try:
    uos.mkdir("my_dir")
except OSError as exc:
    if exc.args[0] == uerrno.EEXIST:
        print("Directory already exists")
```

`uerrno.errorcode`

Dictionary mapping numeric error codes to strings with symbolic error code (see above):
4.1.9 uhashlib — hashing algorithms

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: hashlib.

This module implements binary data hashing algorithms. The exact inventory of available algorithms depends on a board. Among the algorithms which may be implemented:

- SHA256 - The current generation, modern hashing algorithm (of SHA2 series). It is suitable for cryptographically-secure purposes. Included in the MicroPython core and any board is recommended to provide this, unless it has particular code size constraints.

- SHA1 - A previous generation algorithm. Not recommended for new usages, but SHA1 is a part of number of Internet standards and existing applications, so boards targeting network connectivity and interoperability will try to provide this.

- MD5 - A legacy algorithm, not considered cryptographically secure. Only selected boards, targeting interoperability with legacy applications, will offer this.

Constructors

```python
class uhashlib.sha256([data])
Create an SHA256 hasher object and optionally feed data into it.

class uhashlib.sha1([data])
Create an SHA1 hasher object and optionally feed data into it.

class uhashlib.md5([data])
Create an MD5 hasher object and optionally feed data into it.
```

Methods

```python
hash.update(data)
Feed more binary data into hash.

hash.digest()
Return hash for all data passed through hash, as a bytes object. After this method is called, more data cannot be fed into the hash any longer.

hash.hexdigest()
This method is NOT implemented. Use ubinascii.hexlify(hash.digest()) to achieve a similar effect.
```

4.1.10 uheapq — heap queue algorithm

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: heapq.

This module implements the heap queue algorithm.

A heap queue is simply a list that has its elements stored in a certain way.
MicroPython Documentation, Release 1.9.4

Functions

```
heapq.heappush(heap, item)
```
Push the item onto the heap.

```
heapq.heappop(heap)
```
Pop the first item from the heap, and return it. Raises IndexError if heap is empty.

```
heapq.heapify(x)
```
Convert the list x into a heap. This is an in-place operation.

4.1.11 uio – input/output streams

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: io.

This module contains additional types of stream (file-like) objects and helper functions.

Conceptual hierarchy

Difference to CPython

Conceptual hierarchy of stream base classes is simplified in MicroPython, as described in this section.

(_abstract) base stream classes, which serve as a foundation for behavior of all the concrete classes, adhere to few dichotomies (pair-wise classifications) in CPython. In MicroPython, they are somewhat simplified and made implicit to achieve higher efficiencies and save resources.

An important dichotomy in CPython is unbuffered vs buffered streams. In MicroPython, all streams are currently unbuffered. This is because all modern OSes, and even many RTOSEs and filesystem drivers already perform buffering on their side. Adding another layer of buffering is counter-productive (an issue known as “bufferbloat”) and takes precious memory. Note that there still cases where buffering may be useful, so we may introduce optional buffering support at a later time.

But in CPython, another important dichotomy is tied with “bufferedness” - it’s whether a stream may incur short read/writes or not. A short read is when a user asks e.g. 10 bytes from a stream, but gets less, similarly for writes. In CPython, unbuffered streams are automatically short operation susceptible, while buffered are guarantee against them. The no short read/writes is an important trait, as it allows to develop more concise and efficient programs - something which is highly desirable for MicroPython. So, while MicroPython doesn’t support buffered streams, it still provides for no-short-operations streams. Whether there will be short operations or not depends on each particular class’ needs, but developers are strongly advised to favor no-short-operations behavior for the reasons stated above. For example, MicroPython sockets are guaranteed to avoid short read/writes. Actually, at this time, there is no example of a short-operations stream class in the core, and one would be a port-specific class, where such a need is governed by hardware peculiarities.

The no-short-operations behavior gets tricky in case of non-blocking streams, blocking vs non-blocking behavior being another CPython dichotomy, fully supported by MicroPython. Non-blocking streams never wait for data either to arrive or be written - they read/write whatever possible, or signal lack of data (or ability to write data). Clearly, this conflicts with “no-short-operations” policy, and indeed, a case of non-blocking buffered (and this no-short-ops) streams is convoluted in CPython - in some places, such combination is prohibited, in some it’s undefined or just not documented, in some cases it raises verbose exceptions. The matter is much simpler in MicroPython: non-blocking stream are important for efficient asynchronous operations, so this property prevails on the “no-short-ops” one. So, while blocking streams will avoid short reads/writes whenever possible (the only case to get a short read is if end of
file is reached, or in case of error (but errors don’t return short data, but raise exceptions)), non-blocking streams may
produce short data to avoid blocking the operation.

The final dichotomy is binary vs text streams. MicroPython of course supports these, but while in CPython text
streams are inherently buffered, they aren’t in MicroPython. (Indeed, that’s one of the cases for which we may
introduce buffering support.)

Note that for efficiency, MicroPython doesn’t provide abstract base classes corresponding to the hierarchy above, and
it’s not possible to implement, or subclass, a stream class in pure Python.

Functions

```python
uio.open(name, mode='r', **kwargs)
```

Open a file. Built-in `open()` function is aliased to this function. All ports (which provide access to file system)
are required to support `mode` parameter, but support for other arguments vary by port.

Classes

class uio.FileIO(...)

This is type of a file open in binary mode, e.g. using `open(name, "rb")`. You should not instantiate this
class directly.

class uio.TextIOWrapper(...)

This is type of a file open in text mode, e.g. using `open(name, "rt")`. You should not instantiate this class
directly.

class uio.StringIO([string])

class uio.BytesIO([string])

In-memory file-like objects for input/output. `StringIO` is used for text-mode I/O (similar to a normal file
opened with “t” modifier). `BytesIO` is used for binary-mode I/O (similar to a normal file opened with “b”
modifier). Initial contents of file-like objects can be specified with `string` parameter (should be normal string
for `StringIO` or bytes object for `BytesIO`). All the usual file methods like `read()`, `write()`, `seek()`,
`flush()`, `close()` are available on these objects, and additionally, a following method:

```python
getvalue()
```

Get the current contents of the underlying buffer which holds data.

4.1.12 ujson – JSON encoding and decoding

This module implements a subset of the corresponding CPython module, as described below. For more information,
refer to the original CPython documentation: json.

This modules allows to convert between Python objects and the JSON data format.

Functions

```python
ujson.dump(obj, stream)
```

Serialise `obj` to a JSON string, writing it to the given `stream`.

```python
ujson.dumps(obj)
```

Return `obj` represented as a JSON string.
ujson.load(stream)
Parse the given stream, interpreting it as a JSON string and deserialising the data to a Python object. The resulting object is returned.

Parsing continues until end-of-file is encountered. A ValueError is raised if the data in stream is not correctly formed.

ujson.loads(str)
Parse the JSON str and return an object. Raises ValueError if the string is not correctly formed.

4.1.13 uos – basic “operating system” services

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: os.

The uos module contains functions for filesystem access and mounting, terminal redirection and duplication, and the uname and urandom functions.

General functions

uos.uname()
Return a tuple (possibly a named tuple) containing information about the underlying machine and/or its operating system. The tuple has five fields in the following order, each of them being a string:

- sysname – the name of the underlying system
- nodename – the network name (can be the same as sysname)
- release – the version of the underlying system
- version – the MicroPython version and build date
- machine – an identifier for the underlying hardware (eg board, CPU)

uos.urandom(n)
Return a bytes object with n random bytes. Whenever possible, it is generated by the hardware random number generator.

Filesystem access

uos.chdir(path)
Change current directory.

uos.getcwd()
Get the current directory.

uos.ILISTDIR([dir])
This function returns an iterator which then yields tuples corresponding to the entries in the directory that it is listing. With no argument it lists the current directory, otherwise it lists the directory given by dir.

The tuples have the form (name, type, inode, size):

- name is a string (or bytes if dir is a bytes object) and is the name of the entry;
- type is an integer that specifies the type of the entry, with 0x4000 for directories and 0x8000 for regular files;
- inode is an integer corresponding to the inode of the file, and may be 0 for filesystems that don’t have such a notion.
• Some platforms may return a 4-tuple that includes the entry’s size. For file entries, size is an integer representing the size of the file or -1 if unknown. Its meaning is currently undefined for directory entries.

```python
uos.listdir([dir])
With no argument, list the current directory. Otherwise list the given directory.
```

```python
uos.mkdir(path)
Create a new directory.
```

```python
uos.remove(path)
Remove a file.
```

```python
uos.rmdir(path)
Remove a directory.
```

```python
uos.rename(old_path, new_path)
Rename a file.
```

```python
uos.stat(path)
Get the status of a file or directory.
```

```python
uos.statvfs(path)
Get the status of a filesystem.

Returns a tuple with the filesystem information in the following order:

• f_bsize – file system block size
• f_frsize – fragment size
• f_blocks – size of fs in f_frsize units
• f_bfree – number of free blocks
• f_bavail – number of free blocks for unprivileged users
• f_files – number of inodes
• f_ffree – number of free inodes
• f_favail – number of free inodes for unprivileged users
• f_flag – mount flags
• f_namemax – maximum filename length

Parameters related to inodes: f_files, f_ffree, f_favail and the f_flag parameter may return 0 as they can be unavailable in a port-specific implementation.
```

```python
uos.sync()
Sync all filesystems.
```

### Terminal redirection and duplication

```python
uos.dupterm(stream_object, index=0)
Duplicate or switch the MicroPython terminal (the REPL) on the given stream-like object. The stream object argument must implement the readinto() and write() methods. The stream should be in non-blocking mode and readinto() should return None if there is no data available for reading.

After calling this function all terminal output is repeated on this stream, and any input that is available on the stream is passed on to the terminal input.
```
The `index` parameter should be a non-negative integer and specifies which duplication slot is set. A given port may implement more than one slot (slot 0 will always be available) and in that case terminal input and output is duplicated on all the slots that are set.

If `None` is passed as the `stream_object` then duplication is cancelled on the slot given by `index`.

The function returns the previous stream-like object in the given slot.

**Filesystem mounting**

Some ports provide a Virtual Filesystem (VFS) and the ability to mount multiple “real” filesystems within this VFS. Filesystem objects can be mounted at either the root of the VFS, or at a subdirectory that lives in the root. This allows dynamic and flexible configuration of the filesystem that is seen by Python programs. Ports that have this functionality provide the `mount()` and `umount()` functions, and possibly various filesystem implementations represented by VFS classes.

```python
uos.mount (fsobj, mount_point, *, readonly)
```

Mount the filesystem object `fsobj` at the location in the VFS given by the `mount_point` string. `fsobj` can be a a VFS object that has a `mount()` method, or a block device. If it’s a block device then the filesystem type is automatically detected (an exception is raised if no filesystem was recognised). `mount_point` may be `'/'` to mount `fsobj` at the root, or `'/<name>'` to mount it at a subdirectory under the root.

If `readonly` is `True` then the filesystem is mounted read-only.

During the mount process the method `mount()` is called on the filesystem object.

Will raise `OSError(EPERM)` if `mount_point` is already mounted.

```python
uos.umount (mount_point)
```

Unmount a filesystem. `mount_point` can be a string naming the mount location, or a previously-mounted filesystem object. During the unmount process the method `umount()` is called on the filesystem object.

Will raise `OSError(EINVAL)` if `mount_point` is not found.

```python
class uos.VfsFat (block_dev)
```

Create a filesystem object that uses the FAT filesystem format. Storage of the FAT filesystem is provided by `block_dev`. Objects created by this constructor can be mounted using `mount()`.

```python
static mkfs (block_dev)
```

Build a FAT filesystem on `block_dev`.

**Block devices**

A block device is an object which implements the block protocol, which is a set of methods described below by the `AbstractBlockDev` class. A concrete implementation of this class will usually allow access to the memory-like functionality a piece of hardware (like flash memory). A block device can be used by a particular filesystem driver to store the data for its filesystem.

```python
class uos.AbstractBlockDev (...)
```

Construct a block device object. The parameters to the constructor are dependent on the specific block device.

```python
readblocks (block_num, buf)
```

Starting at `block_num`, read blocks from the device into `buf` (an array of bytes). The number of blocks to read is given by the length of `buf`, which will be a multiple of the block size.

```python
writeblocks (block_num, buf)
```

Starting at `block_num`, write blocks from `buf` (an array of bytes) to the device. The number of blocks to write is given by the length of `buf`, which will be a multiple of the block size.
ioctl \((op, arg)\)
Control the block device and query its parameters. The operation to perform is given by \(op\) which is one of the following integers:

- 1 – initialise the device \((arg\ is\ unused)\)
- 2 – shutdown the device \((arg\ is\ unused)\)
- 3 – sync the device \((arg\ is\ unused)\)
- 4 – get a count of the number of blocks, should return an integer \((arg\ is\ unused)\)
- 5 – get the number of bytes in a block, should return an integer, or \texttt{None} in which case the default value of 512 is used \((arg\ is\ unused)\)

By way of example, the following class will implement a block device that stores its data in RAM using a \texttt{bytearray}:

```python
class RAMBlockDev:
    def __init__(self, block_size, num_blocks):
        self.block_size = block_size
        self.data = bytearray(block_size * num_blocks)

    def readblocks(self, block_num, buf):
        for i in range(len(buf)):
            buf[i] = self.data[block_num * self.block_size + i]

    def writeblocks(self, block_num, buf):
        for i in range(len(buf)):
            self.data[block_num * self.block_size + i] = buf[i]

    def ioctl(self, op, arg):
        if op == 4:  # get number of blocks
            return len(self.data) // self.block_size
        if op == 5:  # get block size
            return self.block_size
```

It can be used as follows:

```python
import uos

bdev = RAMBlockDev(512, 50)
uos.VfsFat.mkfs(bdev)
vfs = uos.VfsFat(bdev)
uos.mount(vfs, '/ramdisk')
```

### 4.1.14 \texttt{ure} – simple regular expressions

This module implements a subset of the corresponding \texttt{CPython} module, as described below. For more information, refer to the original \texttt{CPython} documentation: \texttt{re}.

This module implements regular expression operations. Regular expression syntax supported is a subset of CPython \texttt{re} module (and actually is a subset of POSIX extended regular expressions).

Supported operators are:
- '.' Match any character.
- '[...]' Match set of characters. Individual characters and ranges are supported, including negated sets (e.g. `[^a-c]`).
'^'
'§'
'?'
'*'
'+'
'??'
'*?'
'+?'|'
'(...)' Grouping. Each group is capturing (a substring it captures can be accessed with `match.group()` method).

**NOT SUPPORTED:** Counted repetitions (\{m,n\}), more advanced assertions (\b, \B), named groups (\(? P{name}>...)\), non-capturing groups (\(?:\...)\), etc.

### Functions

`ure.compile(regex_str[, flags])`
Compile regular expression, return `regex` object.

`ure.match(regex_str, string)`
Compile `regex_str` and match against `string`. Match always happens from starting position in a string.

`ure.search(regex_str, string)`
Compile `regex_str` and search it in a `string`. Unlike `match`, this will search string for first position which matches regex (which still may be 0 if regex is anchored).

`ure.DEBUG`  
Flag value, display debug information about compiled expression. (Availability depends on MicroPython port.)

### Regex objects

Compiled regular expression. Instances of this class are created using `ure.compile()`.

`regex.match(string)`
`regex.search(string)`
Similar to the module-level functions `match()` and `search()`. Using methods is (much) more efficient if the same regex is applied to multiple strings.

`regex.split(string, max_split=-1)`
Split a `string` using regex. If `max_split` is given, it specifies maximum number of splits to perform. Returns list of strings (there may be up to `max_split+1` elements if it’s specified).

### Match objects

Match objects as returned by `match()` and `search()` methods.

`match.group([index])`
Return matching (substring. `index` is 0 for entire match, 1 and above for each capturing group. Only numeric groups are supported.

4.1. Python standard libraries and micro-libraries 49
4.1.15 uselect – wait for events on a set of streams

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: select.

This module provides functions to efficiently wait for events on multiple streams (select streams which are ready for operations).

Functions

uselect.poll()
Create an instance of the Poll class.

uselect.select(rlist, wlist, xlist[, timeout])
Wait for activity on a set of objects.

This function is provided by some MicroPython ports for compatibility and is not efficient. Usage of Poll is recommended instead.

class Poll

Methods

poll.register(obj[, eventmask])
Register stream obj for polling. eventmask is logical OR of:

- uselect.POLLIN - data available for reading
- uselect.POLLOUT - more data can be written

Note that flags like uselect.POLLHUP and uselect.POLLERR are not valid as input eventmask (these are unsolicited events which will be returned from poll() regardless of whether they are asked for). This semantics is per POSIX.

eventmask defaults to uselect.POLLIN | uselect.POLLOUT.

poll.unregister(obj)
Unregister obj from polling.

poll.modify(obj, eventmask)
Modify the eventmask for obj.

poll.poll(timeout=-1)
Wait for at least one of the registered objects to become ready or have an exceptional condition, with optional timeout in milliseconds (if timeout arg is not specified or -1, there is no timeout).

Returns list of (obj, event,...) tuples. There may be other elements in tuple, depending on a platform and version, so don’t assume that its size is 2. The event element specifies which events happened with a stream and is a combination of uselect.POLL* constants described above. Note that flags uselect.POLLHUP and uselect.POLLERR can be returned at any time (even if were not asked for), and must be acted on accordingly (the corresponding stream unregistered from poll and likely closed), because otherwise all further invocations of poll() may return immediately with these flags set for this stream again.

In case of timeout, an empty list is returned.

Difference to CPython
Tuples returned may contain more than 2 elements as described above.

```
import ipoll
poll.ipoll(timeout=-1, flags=0)
```

Like `poll.poll()`, but instead returns an iterator which yields a `callee-owned tuple`. This function provides an efficient, allocation-free way to poll on streams.

If `flags` is 1, one-shot behavior for events is employed: streams for which events happened will have their event masks automatically reset (equivalent to `poll.modify(obj, 0)`), so new events for such a stream won’t be processed until new mask is set with `poll.modify()`. This behavior is useful for asynchronous I/O schedulers.

**Difference to CPython**

This function is a MicroPython extension.

### 4.1.16 usocket – socket module

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: `socket`.

This module provides access to the BSD socket interface.

**Difference to CPython**

For efficiency and consistency, socket objects in MicroPython implement a stream (file-like) interface directly. In CPython, you need to convert a socket to a file-like object using `makefile()` method. This method is still supported by MicroPython (but is a no-op), so where compatibility with CPython matters, be sure to use it.

**Socket address format(s)**

The native socket address format of the `usocket` module is an opaque data type returned by `getaddrinfo` function, which must be used to resolve textual address (including numeric addresses):

```python
sockaddr = usocket.getaddrinfo('www.micropython.org', 80)[0][-1]
# You must use getaddrinfo() even for numeric addresses
sockaddr = usocket.getaddrinfo('127.0.0.1', 80)[0][-1]
# Now you can use that address
sock.connect(addr)
```

Using `getaddrinfo` is the most efficient (both in terms of memory and processing power) and portable way to work with addresses.

However, `socket` module (note the difference with native MicroPython `usocket` module described here) provides CPython-compatible way to specify addresses using tuples, as described below. Note that depending on a MicroPython port, `socket` module can be built-in or need to be installed from `micropython-lib` (as in the case of MicroPython Unix port), and some ports still accept only numeric addresses in the tuple format, and require to use `getaddrinfo` function to resolve domain names.

Summing up:

- Always use `getaddrinfo` when writing portable applications.
- Tuple addresses described below can be used as a shortcut for quick hacks and interactive use, if your port supports them.
Tuple address format for `socket` module:

- IPv4: `(ipv4_address, port)`, where `ipv4_address` is a string with dot-notation numeric IPv4 address, e.g. "8.8.8.8", and `port` is an integer port number in the range 1-65535. Note the domain names are not accepted as `ipv4_address`, they should be resolved first using `usocket.getaddrinfo()`.

- IPv6: `(ipv6_address, port, flowinfo, scopeid)`, where `ipv6_address` is a string with colon-notation numeric IPv6 address, e.g. "2001:db8::1", and `port` is an integer port number in the range 1-65535. `flowinfo` must be 0. `scopeid` is the interface scope identifier for link-local addresses. Note the domain names are not accepted as `ipv6_address`, they should be resolved first using `usocket.getaddrinfo()`. Availability of IPv6 support depends on a MicroPython port.

Functions

`usocket.socket`(af=AF_INET, type=SOCK_STREAM, proto=IPPROTO_TCP)
Create a new socket using the given address family, socket type and protocol number. Note that specifying `proto` in most cases is not required (and not recommended, as some MicroPython ports may omit IPPROTO_* constants). Instead, `type` argument will select needed protocol automatically:

```python
# Create STREAM TCP socket
socket(AF_INET, SOCK_STREAM)
# Create DGRAM UDP socket
socket(AF_INET, SOCK_DGRAM)
```

`usocket.getaddrinfo`(host, port)
Translate the host/port argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. The list of 5-tuples has following structure:

```
(family, type, proto, canonname, sockaddr)
```

The following example shows how to connect to a given url:

```python
s = usocket.socket()
s.connect(usocket.getaddrinfo('www.micropython.org', 80)[0][-1])
```

**Difference to CPython**

CPython raises a `socket.gaierror` exception (OSError subclass) in case of error in this function. MicroPython doesn’t have `socket.gaierror` and raises OSError directly. Note that error numbers of `getaddrinfo()` form a separate namespace and may not match error numbers from the `uerrno` module. To distinguish `getaddrinfo()` errors, they are represented by negative numbers, whereas standard system errors are positive numbers (error numbers are accessible using e.args[0] property from an exception object). The use of negative values is a provisional detail which may change in the future.

`usocket.inet_ntop`(af, bin_addr)
Convert a binary network address `bin_addr` of the given address family `af` to a textual representation:

```python
>>> usocket.inet_ntop(usocket.AF_INET, b"\x7f\x00\x00\x01")
'127.0.0.1'
```

`usocket.inet_pton`(af, txt_addr)
Convert a textual network address `txt_addr` of the given address family `af` to a binary representation:

```python
>>> usocket.inet_pton(usocket.AF_INET, "1.2.3.4")
b'\x01\x02\x03\x04'
```
Constants

usocket.AF_INET
usocket.AF_INET6
   Address family types. Availability depends on a particular MicroPython port.

usocket.SOCK_STREAM
usocket.SOCK_DGRAM
   Socket types.

usocket.IPPROTO_UDP
usocket.IPPROTO_TCP
   IP protocol numbers. Availability depends on a particular MicroPython port. Note that you don’t need
to specify these in a call to usocket.socket(), because SOCK_STREAM socket type automatically selects
IPPROTO_TCP, and SOCK_DGRAM - IPPROTO_UDP. Thus, the only real use of these constants is as an
argument to setsockopt().

usocket.SOL_*
   Socket option levels (an argument to setsockopt()). The exact inventory depends on a MicroPython
port.

usocket.SO_*
   Socket options (an argument to setsockopt()). The exact inventory depends on a MicroPython port.

Constants specific to WiPy:

usocket.IPPROTO_SEC
   Special protocol value to create SSL-compatible socket.

class socket

Methods

socket.close()
   Mark the socket closed and release all resources. Once that happens, all future operations on the socket object
will fail. The remote end will receive EOF indication if supported by protocol.

Sockets are automatically closed when they are garbage-collected, but it is recommended to close() them
explicitly as soon you finished working with them.

socket.bind(address)
   Bind the socket to address. The socket must not already be bound.

socket.listen([backlog])
   Enable a server to accept connections. If backlog is specified, it must be at least 0 (if it’s lower, it will be set to 0);
and specifies the number of unaccepted connections that the system will allow before refusing new connections.
If not specified, a default reasonable value is chosen.

socket.accept()
   Accept a connection. The socket must be bound to an address and listening for connections. The return value is
a pair (conn, address) where conn is a new socket object usable to send and receive data on the connection, and
address is the address bound to the socket on the other end of the connection.

socket.connect(address)
   Connect to a remote socket at address.

socket.send(bytes)
   Send data to the socket. The socket must be connected to a remote socket. Returns number of bytes sent, which
may be smaller than the length of data (“short write”).
socket.sendall(bytes)
Send all data to the socket. The socket must be connected to a remote socket. Unlike send(), this method will try to send all of data, by sending data chunk by chunk consecutively.

The behavior of this method on non-blocking sockets is undefined. Due to this, on MicroPython, it's recommended to use write() method instead, which has the same “no short writes” policy for blocking sockets, and will return number of bytes sent on non-blocking sockets.

socket.recv(bufsize)
Receive data from the socket. The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by bufsize.

socket.sendto(bytes, address)
Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by address.

socket.recvfrom(bufsize)
Receive data from the socket. The return value is a pair (bytes, address) where bytes is a bytes object representing the data received and address is the address of the socket sending the data.

socket.setsockopt(level, optname, value)
Set the value of the given socket option. The needed symbolic constants are defined in the socket module (SO_* etc.). The value can be an integer or a bytes-like object representing a buffer.

socket.settimeout(value)
Note: Not every port supports this method, see below.

Set a timeout on blocking socket operations. The value argument can be a nonnegative floating point number expressing seconds, or None. If a non-zero value is given, subsequent socket operations will raise an OSError exception if the timeout period value has elapsed before the operation has completed. If zero is given, the socket is put in non-blocking mode. If None is given, the socket is put in blocking mode.

Not every MicroPython port supports this method. A more portable and generic solution is to use uselect.poll object. This allows to wait on multiple objects at the same time (and not just on sockets, but on generic stream objects which support polling). Example:

```
# Instead of:
s.settimeout(1.0)  # time in seconds
s.read(10)        # may timeout

# Use:
poller = uselect.poll()
poller.register(s, uselect.POLLIN)
res = poller.poll(1000)  # time in milliseconds
if not res:
    # s is still not ready for input, i.e. operation timed out
```

Difference to CPython

CPython raises a socket.timeout exception in case of timeout, which is an OSError subclass. MicroPython raises an OSError directly instead. If you use except OSError: to catch the exception, your code will work both in MicroPython and CPython.

socket.setblocking(flag)
Set blocking or non-blocking mode of the socket: if flag is false, the socket is set to non-blocking, else to blocking mode.

This method is a shorthand for certain settimeout() calls:
• `sock.setblocking(True)` is equivalent to `sock.settimeout(None)`
• `sock.setblocking(False)` is equivalent to `sock.settimeout(0)`

`socket.makefile(mode='rb', buffering=0)`
Return a file object associated with the socket. The exact returned type depends on the arguments given to `makefile()`. The support is limited to binary modes only (‘rb’, ‘wb’, and ‘rwb’). CPython’s arguments: `encoding`, `errors` and `newline` are not supported.

**Difference to CPython**
As MicroPython doesn’t support buffered streams, values of `buffering` parameter is ignored and treated as if it was 0 (unbuffered).

**Difference to CPython**
Closing the file object returned by `makefile()` WILL close the original socket as well.

`socket.read([size])`
Read up to size bytes from the socket. Return a bytes object. If `size` is not given, it reads all data available from the socket until EOF; as such the method will not return until the socket is closed. This function tries to read as much data as requested (no “short reads”). This may be not possible with non-blocking socket though, and then less data will be returned.

`socket.readinto(buf[, nbytes])`
Read bytes into the `buf`. If `nbytes` is specified then read at most that many bytes. Otherwise, read at most `len(buf)` bytes. Just as `read()`, this method follows “no short reads” policy.

Return value: number of bytes read and stored into `buf`.

`socket.readline()`
Read a line, ending in a newline character.
Return value: the line read.

`socket.write(buf)`
Write the buffer of bytes to the socket. This function will try to write all data to a socket (no “short writes”). This may be not possible with a non-blocking socket though, and returned value will be less than the length of `buf`.
Return value: number of bytes written.

**exception usocket.error**
MicroPython does NOT have this exception.

**Difference to CPython**
CPython used to have a `socket.error` exception which is now deprecated, and is an alias of `OSError`. In MicroPython, use `OSError` directly.

### 4.1.17 `ussl` – SSL/TLS module

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: `ssl`.
This module provides access to Transport Layer Security (previously and widely known as “Secure Sockets Layer”) encryption and peer authentication facilities for network sockets, both client-side and server-side.

**Functions**

```python
ussl.wrap_socket(sock, server_side=False, keyfile=None, certfile=None, cert_reqs=CERT_NONE, ca_certs=None)
```

Takes a stream `sock` (usually `usocket.socket` instance of `SOCK_STREAM` type), and returns an instance of `ssl.SSLSocket`, which wraps the underlying stream in an SSL context. Returned object has the usual stream interface methods like `read()`, `write()`, etc. In MicroPython, the returned object does not expose socket interface and methods like `recv()`, `send()`. In particular, a server-side SSL socket should be created from a normal socket returned from `accept()` on a non-SSL listening server socket.

Depending on the underlying module implementation in a particular MicroPython port, some or all keyword arguments above may be not supported.

**Warning:** Some implementations of `ussl` module do NOT validate server certificates, which makes an SSL connection established prone to man-in-the-middle attacks.

**Exceptions**

```python
ssl.SSLError
```

This exception does NOT exist. Instead its base class, `OSError`, is used.

**Constants**

```python
ussl.CERT_NONE
ussl.CERT_OPTIONAL
ussl.CERT_REQUIRED
```

Supported values for `cert_reqs` parameter.

### 4.1.18 ustruct – pack and unpack primitive data types

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: `struct`.

Supported size/byte order prefixes: @, <, >, !.

Supported format codes: b, B, h, H, i, I, l, L, q, Q, s, P, f, d (the latter 2 depending on the floating-point support).

**Functions**

```python
ussl.pack(fmt)
ussl.pack_into(fmt, buffer, offset, v1, v2, ...)
```

Pack the values `v1`, `v2`, … according to the format string `fmt`. The return value is a bytes object encoding the values.

```python
ussl.pack_into(fmt, buffer, offset, v1, v2, ...)
```

Pack the values `v1`, `v2`, … according to the format string `fmt` into a `buffer` starting at `offset`. `offset` may be negative to count from the end of `buffer`.
ustruct.\texttt{unpack} \((fmt, data)\)

Unpack from the \textit{data} according to the format string \textit{fmt}. The return value is a tuple of the unpacked values.

\textbf{ustruct.\texttt{unpack_from}} \((fmt, data, offset=0)\)

Unpack from the \textit{data} starting at \textit{offset} according to the format string \textit{fmt}. \textit{offset} may be negative to count from the end of buffer. The return value is a tuple of the unpacked values.

\subsection*{4.1.19 utime – time related functions}

\textit{This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: \texttt{time}.}

The \texttt{utime} module provides functions for getting the current time and date, measuring time intervals, and for delays.

\textbf{Time Epoch}: Unix port uses standard for POSIX systems epoch of 1970-01-01 00:00:00 UTC. However, embedded ports use epoch of 2000-01-01 00:00:00 UTC.

\textbf{Maintaining actual calendar date/time}: This requires a Real Time Clock (RTC). On systems with underlying OS (including some RTOS), an RTC may be implicit. Setting and maintaining actual calendar time is responsibility of OS/RTOS and is done outside of MicroPython, it just uses OS API to query date/time. On baremetal ports however system time depends on \texttt{machine.RTC()} object. The current calendar time may be set using \texttt{machine.RTC()}. \texttt{datetime(tuple)} function, and maintained by following means:

\begin{itemize}
  \item By a backup battery (which may be an additional, optional component for a particular board).
  \item Using networked time protocol (requires setup by a port/user).
  \item Set manually by a user on each power-up (many boards then maintain RTC time across hard resets, though some may require setting it again in such case).
\end{itemize}

If actual calendar time is not maintained with a system/MicroPython RTC, functions below which require reference to current absolute time may behave not as expected.

\textbf{Functions}

\texttt{utime.localtime} \([\text{secs}]\)

Convert a time expressed in seconds since the Epoch (see above) into an 8-tuple which contains: (year, month, mday, hour, minute, second, weekday, yearday) If \texttt{secs} is not provided or None, then the current time from the RTC is used.

\begin{itemize}
  \item year includes the century (for example 2014).
  \item month is 1-12
  \item mday is 1-31
  \item hour is 0-23
  \item minute is 0-59
  \item second is 0-59
  \item weekday is 0-6 for Mon-Sun
  \item yearday is 1-366
\end{itemize}

\texttt{utime.mktime} ()

This is inverse function of \texttt{localtime}. It’s argument is a full 8-tuple which expresses a time as per \texttt{localtime}. It returns an integer which is the number of seconds since Jan 1, 2000.
utime.sleep(seconds)
Sleep for the given number of seconds. Some boards may accept seconds as a floating-point number to sleep for a fractional number of seconds. Note that other boards may not accept a floating-point argument, for compatibility with them use sleep_ms() and sleep_us() functions.

utime.sleep_ms(ms)
Delay for given number of milliseconds, should be positive or 0.

utime.sleep_us(us)
Delay for given number of microseconds, should be positive or 0.

utime.ticks_ms()
Returns an increasing millisecond counter with an arbitrary reference point, that wraps around after some value. The wrap-around value is not explicitly exposed, but we will refer to it as TICKS_MAX to simplify discussion. Period of the values is TICKS_PERIOD = TICKS_MAX + 1. TICKS_PERIOD is guaranteed to be a power of two, but otherwise may differ from port to port. The same period value is used for all of ticks_ms(), ticks_us(), ticks_cpu() functions (for simplicity). Thus, these functions will return a value in range [0 .. TICKS_MAX], inclusive, total TICKS_PERIOD values. Note that only non-negative values are used. For the most part, you should treat values returned by these functions as opaque. The only operations available for them are ticks_diff() and ticks_add() functions described below.

Note: Performing standard mathematical operations (+, -) or relational operators (<, <=, >, >=) directly on these value will lead to invalid result. Performing mathematical operations and then passing their results as arguments to ticks_diff() or ticks_add() will also lead to invalid results from the latter functions.

utime.ticks_us()
Just like ticks_ms() above, but in microseconds.

utime.ticks_cpu()
Similar to ticks_ms() and ticks_us(), but with the highest possible resolution in the system. This is usually CPU clocks, and that’s why the function is named that way. But it doesn’t have to be a CPU clock, some other timing source available in a system (e.g. high-resolution timer) can be used instead. The exact timing unit (resolution) of this function is not specified on utime module level, but documentation for a specific port may provide more specific information. This function is intended for very fine benchmarking or very tight real-time loops. Avoid using it in portable code.

Availability: Not every port implements this function.

utime.ticks_add(ticks, delta)
Offset ticks value by a given number, which can be either positive or negative. Given a ticks value, this function allows to calculate ticks value delta ticks before or after it, following modular-arithmetic definition of tick values (see ticks_ms() above). ticks parameter must be a direct result of call to ticks_ms(), ticks_us(), or ticks_cpu() functions (or from previous call to ticks_add()). However, delta can be an arbitrary integer number or numeric expression. ticks_add() is useful for calculating deadlines for events/tasks. (Note: you must use ticks_diff() function to work with deadlines.)

Examples:

```python
# Find out what ticks value there was 100ms ago
print(ticks_add(time.ticks_ms(), -100))

# Calculate deadline for operation and test for it
deadline = ticks_add(time.ticks_ms(), 200)
while ticks_diff(deadline, time.ticks_ms()) > 0:
    do_a_little_of_something()

# Find out TICKS_MAX used by this port
print(ticks_add(0, -1))
```
**utime.ticks_diff(ticks1, ticks2)**

Measure ticks difference between values returned from `ticks_ms()`, `ticks_us()`, or `ticks_cpu()` functions, as a signed value which may wrap around.

The argument order is the same as for subtraction operator, `ticks_diff(ticks1, ticks2)` has the same meaning as `ticks1 - ticks2`. However, values returned by `ticks_ms()`, etc. functions may wrap around, so directly using subtraction on them will produce incorrect result. That is why `ticks_diff()` is needed, it implements modular (or more specifically, ring) arithmetics to produce correct result even for wrap-around values (as long as they not too distant inbetween, see below). The function returns signed value in the range [-`TICKS_PERIOD/2` .. `TICKS_PERIOD/2-1`] (that’s a typical range definition for two’s-complement signed binary integers). If the result is negative, it means that `ticks1` occurred earlier in time than `ticks2`. Otherwise, it means that `ticks1` occurred after `ticks2`. This holds only if `ticks1` and `ticks2` are apart from each other for no more than `TICKS_PERIOD/2-1` ticks. If that does not hold, incorrect result will be returned. Specifically, if two tick values are apart for `TICKS_PERIOD/2-1` ticks, that value will be returned by the function. However, if `TICKS_PERIOD/2` of real-time ticks has passed between them, the function will return `-TICKS_PERIOD/2` instead, i.e. result value will wrap around to the negative range of possible values.

Informal rationale of the constraints above: Suppose you are locked in a room with no means to monitor passing of time except a standard 12-notch clock. Then if you look at dial-plate now, and don’t look again for another 13 hours (e.g., if you fall for a long sleep), then once you finally look again, it may seem to you that only 1 hour has passed. To avoid this mistake, just look at the clock regularly. Your application should do the same. “Too long sleep” metaphor also maps directly to application behavior: don’t let your application run any single task for too long. Run tasks in steps, and do time-keeping inbetween.

`ticks_diff()` is designed to accommodate various usage patterns, among them:

- **Polling with timeout.** In this case, the order of events is known, and you will deal only with positive results of `ticks_diff()`:

  ```python
  # Wait for GPIO pin to be asserted, but at most 500us
  start = time.ticks_us()
  while pin.value() == 0:
      if time.ticks_diff(time.ticks_us(), start) > 500:
          raise TimeoutError
  ```

- **Scheduling events.** In this case, `ticks_diff()` result may be negative if an event is overdue:

  ```python
  # This code snippet is not optimized
  now = time.ticks_ms()
  scheduled_time = task.scheduled_time()
  if ticks_diff(scheduled_time, now) > 0:
      print("Too early, let's nap")
      sleep_ms(ticks_diff(scheduled_time, now))
      task.run()
  elif ticks_diff(scheduled_time, now) == 0:
      print("Right at time!")
      task.run()
  elif ticks_diff(scheduled_time, now) < 0:
      print("Oops, running late, tell task to run faster!")
      task.run(run_faster=True)
  ```

Note: Do not pass `time()` values to `ticks_diff()`, you should use normal mathematical operations on them. But note that `time()` may (and will) also overflow. This is known as https://en.wikipedia.org/wiki/Year_2038_problem.

**utime.time()**

Returns the number of seconds, as an integer, since the Epoch, assuming that underlying RTC is set and maintained as described above. If an RTC is not set, this function returns number of seconds since a port-specific
reference point in time (for embedded boards without a battery-backed RTC, usually since power up or reset). If you want to develop portable MicroPython application, you should not rely on this function to provide higher than second precision. If you need higher precision, use `ticks_ms()` and `ticks_us()` functions, if you need calendar time, `localtime()` without an argument is a better choice.

**Difference to CPython**

In CPython, this function returns number of seconds since Unix epoch, 1970-01-01 00:00 UTC, as a floating-point, usually having microsecond precision. With MicroPython, only Unix port uses the same Epoch, and if floating-point precision allows, returns sub-second precision. Embedded hardware usually doesn’t have floating-point precision to represent both long time ranges and subsecond precision, so they use integer value with second precision. Some embedded hardware also lacks battery-powered RTC, so returns number of seconds since last power-up or from other relative, hardware-specific point (e.g. reset).

### 4.1.20 uzlib – zlib decompression

This module implements a subset of the corresponding CPython module, as described below. For more information, refer to the original CPython documentation: zlib.

This module allows to decompress binary data compressed with DEFLATE algorithm (commonly used in zlib library and gzip archiver). Compression is not yet implemented.

**Functions**

```python
uzlib.decompress(data, wbits=0, bufsize=0)
```

Return decompressed `data` as bytes. `wbits` is DEFLATE dictionary window size used during compression (8-15, the dictionary size is power of 2 of that value). Additionally, if value is positive, `data` is assumed to be zlib stream (with zlib header). Otherwise, if it’s negative, it’s assumed to be raw DEFLATE stream. `bufsize` parameter is for compatibility with CPython and is ignored.

```python
class uzlib.DecompIO(stream, wbits=0)
```

Create a stream wrapper which allows transparent decompression of compressed data in another stream. This allows to process compressed streams with data larger than available heap size. In addition to values described in `decompress()`, `wbits` may take values 24..31 (16 + 8..15), meaning that input stream has gzip header.

**Difference to CPython**

This class is MicroPython extension. It’s included on provisional basis and may be changed considerably or removed in later versions.

### 4.2 MicroPython-specific libraries

Functionality specific to the MicroPython implementation is available in the following libraries.

#### 4.2.1 btrees – simple BTree database

The `btrees` module implements a simple key-value database using external storage (disk files, or in general case, a random-access stream). Keys are stored sorted in the database, and besides efficient retrieval by a key value, a database also supports efficient ordered range scans (retrieval of values with the keys in a given range). On the
application interface side, BTree database work as close a possible to a way standard `dict` type works, one notable difference is that both keys and values must be `bytes` objects (so, if you want to store objects of other types, you need to serialize them to `bytes` first).

The module is based on the well-known BerkelyDB library, version 1.xx.

Example:

```python
import btree

# First, we need to open a stream which holds a database
# This is usually a file, but can be in-memory database
# using uio.BytesIO, a raw flash partition, etc.
# Oftentimes, you want to create a database file if it doesn't
# exist and open if it exists. Idiom below takes care of this.
# DO NOT open database with "a+b" access mode.
try:
    f = open("mydb", "r+b")
except OSError:
    f = open("mydb", "w+b")

# Now open a database itself
db = btree.open(f)

# The keys you add will be sorted internally in the database
db[b"3"] = b"three"
db[b"1"] = b"one"
db[b"2"] = b"two"

# Assume that any changes are cached in memory unless
# explicitly flushed (or database closed). Flush database
# at the end of each "transaction".
db.flush()

# Prints b'two'
print(db[b"2"])

# Iterate over sorted keys in the database, starting from b"2"
# until the end of the database, returning only values.
# Mind that arguments passed to values() method are *key* values.
# Prints:
# b'two'
# b'three'
for word in db.values(b"2"):
    print(word)

del db[b"2"]

# No longer true, prints False
print(b"2" in db)

# Prints:
# b"1"
# b"3"
for key in db:
    print(key)

db.close()
```
Functions

btree.open(stream, *, flags=0, pagesize=0, cachesize=0, minkeypage=0)
Open a database from a random-access stream (like an open file). All other parameters are optional and keyword-only, and allow to tweak advanced parameters of the database operation (most users will not need them):

• flags - Currently unused.
• pagesize - Page size used for the nodes in BTree. Acceptable range is 512-65536. If 0, a port-specific default will be used, optimized for port’s memory usage and/or performance.
• cachesize - Suggested memory cache size in bytes. For a board with enough memory using larger values may improve performance. Cache policy is as follows: entire cache is not allocated at once; instead, accessing a new page in database will allocate a memory buffer for it, until value specified by cachesize is reached. Then, these buffers will be managed using LRU (least recently used) policy. More buffers may still be allocated if needed (e.g., if a database contains big keys and/or values). Allocated cache buffers aren’t reclaimed.
• minkeypage - Minimum number of keys to store per page. Default value of 0 equivalent to 2.

Returns a BTree object, which implements a dictionary protocol (set of methods), and some additional methods described below.

Methods

btree.close()
Close the database. It’s mandatory to close the database at the end of processing, as some unwritten data may be still in the cache. Note that this does not close underlying stream with which the database was opened, it should be closed separately (which is also mandatory to make sure that data flushed from buffer to the underlying storage).

btree.flush()
Flush any data in cache to the underlying stream.

btree.__getitem__(key)
btree.get(key, default=None)
btree.__setitem__(key, val)
btree.__delitem__(key)
btree.__contains__(key)
Standard dictionary methods.

btree.__iter__()
A BTree object can be iterated over directly (similar to a dictionary) to get access to all keys in order.

btree.keys([start_key[, end_key[, flags]]])
btree.values([start_key[, end_key[, flags]]])
btree.items([start_key[, end_key[, flags]]])

These methods are similar to standard dictionary methods, but also can take optional parameters to iterate over a key sub-range, instead of the entire database. Note that for all 3 methods, start_key and end_key arguments represent key values. For example, values() method will iterate over values corresponding to they key range given. None values for start_key means “from the first key”, no end_key or its value of None means “until the end of database”. By default, range is inclusive of start_key and exclusive of end_key.
in iteration by passing flags of `btree.INCL`. You can iterate in descending key direction by passing flags of `btree.DESC`. The flags values can be ORed together.

**Constants**

`btree.INCL`
- A flag for `keys()`, `values()`, `items()` methods to specify that scanning should be inclusive of the end key.

`btree.DESC`
- A flag for `keys()`, `values()`, `items()` methods to specify that scanning should be in descending direction of keys.

### 4.2.2 framebuffer — Frame buffer manipulation

This module provides a general frame buffer which can be used to create bitmap images, which can then be sent to a display.

**class FrameBuffer**

The FrameBuffer class provides a pixel buffer which can be drawn upon with pixels, lines, rectangles, text and even other FrameBuffer's. It is useful when generating output for displays.

For example:

```python
import framebuf

# FrameBuffer needs 2 bytes for every RGB565 pixel
fbuf = FrameBuffer(bytearray(10 * 100 * 2), 10, 100, framebuf.RGB565)

fbuf.fill(0)
fbuf.text('MicroPython!', 0, 0, 0xffff)
fbuf.hline(0, 10, 96, 0xffff)
```

**Constructors**

```python
class framebuffer.FrameBuffer(buffer, width, height, format, stride=width)
```

Construct a FrameBuffer object. The parameters are:

- `buffer` is an object with a buffer protocol which must be large enough to contain every pixel defined by the width, height and format of the FrameBuffer.
- `width` is the width of the FrameBuffer in pixels
- `height` is the height of the FrameBuffer in pixels
- `format` specifies the type of pixel used in the FrameBuffer; permissible values are listed under Constants below. These set the number of bits used to encode a color value and the layout of these bits in `buffer`. Where a color value `c` is passed to a method, `c` is a small integer with an encoding that is dependent on the format of the FrameBuffer.
- `stride` is the number of pixels between each horizontal line of pixels in the FrameBuffer. This defaults to `width` but may need adjustments when implementing a FrameBuffer within another larger FrameBuffer or screen. The `buffer` size must accommodate an increased step size.
One must specify valid buffer, width, height, format and optionally stride. Invalid buffer size or dimensions may lead to unexpected errors.

**Drawing primitive shapes**

The following methods draw shapes onto the FrameBuffer.

- **Framebuffer.fill(c)**
  Fill the entire FrameBuffer with the specified color.

- **Framebuffer.pixel(x, y[, c])**
  If c is not given, get the color value of the specified pixel. If c is given, set the specified pixel to the given color.

- **Framebuffer.hline(x, y, w, c)**
- **Framebuffer.vline(x, y, h, c)**
  Draw a line from a set of coordinates using the given color and a thickness of 1 pixel. The line method draws the line up to a second set of coordinates whereas the hline and vline methods draw horizontal and vertical lines respectively up to a given length.

- **Framebuffer.rect(x, y, w, h, c)**
- **Framebuffer.fill_rect(x, y, w, h, c)**
  Draw a rectangle at the given location, size and color. The rect method draws only a 1 pixel outline whereas the fill_rect method draws both the outline and interior.

**Drawing text**

- **Framebuffer.text(s, x, y[, c])**
  Write text to the FrameBuffer using the the coordinates as the upper-left corner of the text. The color of the text can be defined by the optional argument but is otherwise a default value of 1. All characters have dimensions of 8x8 pixels and there is currently no way to change the font.

**Other methods**

- **Framebuffer.scroll(xstep, ystep)**
  Shift the contents of the FrameBuffer by the given vector. This may leave a footprint of the previous colors in the FrameBuffer.

- **Framebuffer.blit(fbuf, x, y[, key])**
  Draw another FrameBuffer on top of the current one at the given coordinates. If key is specified then it should be a color integer and the corresponding color will be considered transparent: all pixels with that color value will not be drawn.

  This method works between FrameBuffer instances utilising different formats, but the resulting colors may be unexpected due to the mismatch in color formats.

**Constants**

- **framebuf.MONO_VLSB**
  Monochrome (1-bit) color format This defines a mapping where the bits in a byte are vertically mapped with bit 0 being nearest the top of the screen. Consequently each byte occupies 8 vertical pixels. Subsequent bytes appear at successive horizontal locations until the rightmost edge is reached. Further bytes are rendered at locations starting at the leftmost edge, 8 pixels lower.
Framebuf.

- **MONO_HLSB**: Monochrome (1-bit) color format. This defines a mapping where the bits in a byte are horizontally mapped. Each byte occupies 8 horizontal pixels with bit 0 being the leftmost. Subsequent bytes appear at successive horizontal locations until the rightmost edge is reached. Further bytes are rendered on the next row, one pixel lower.

- **MONO_HMSB**: Monochrome (1-bit) color format. This defines a mapping where the bits in a byte are horizontally mapped. Each byte occupies 8 horizontal pixels with bit 7 being the leftmost. Subsequent bytes appear at successive horizontal locations until the rightmost edge is reached. Further bytes are rendered on the next row, one pixel lower.

- **RGB565**: Red Green Blue (16-bit, 5+6+5) color format.

- **GS2_HMSB**: Grayscale (2-bit) color format.

- **GS4_HMSB**: Grayscale (4-bit) color format.

- **GS8**: Grayscale (8-bit) color format.

### 4.2.3 machine — functions related to the hardware

The `machine` module contains specific functions related to the hardware on a particular board. Most functions in this module allow to achieve direct and unrestricted access to and control of hardware blocks on a system (like CPU, timers, buses, etc.). Used incorrectly, this can lead to malfunction, lockups, crashes of your board, and in extreme cases, hardware damage. A note of callbacks used by functions and class methods of `machine` module: all these callbacks should be considered as executing in an interrupt context. This is true for both physical devices with IDs >= 0 and “virtual” devices with negative IDs like -1 (these “virtual” devices are still thin shims on top of real hardware and real hardware interrupts). See [Writing interrupt handlers](#).

#### Reset related functions

- **machine.reset()**: Resets the device in a manner similar to pushing the external RESET button.

- **machine.reset_cause()**: Get the reset cause. See `constants` for the possible return values.

#### Interrupt related functions

- **machine.disable_irq()**: Disable interrupt requests. Returns the previous IRQ state which should be considered an opaque value. This return value should be passed to the `enable_irq()` function to restore interrupts to their original state, before `disable_irq()` was called.

- **machine.enable_irq(state)**: Re-enable interrupt requests. The `state` parameter should be the value that was returned from the most recent call to the `disable_irq()` function.

#### Power related functions

- **machine.freq()**: Returns CPU frequency in hertz.
machine.idle()
Gates the clock to the CPU, useful to reduce power consumption at any time during short or long periods. Peripherals continue working and execution resumes as soon as any interrupt is triggered (on many ports this includes system timer interrupt occurring at regular intervals on the order of millisecond).

machine.sleep()
Stops the CPU and disables all peripherals except for WLAN. Execution is resumed from the point where the sleep was requested. For wake up to actually happen, wake sources should be configured first.

machine.deepsleep()
Stops the CPU and all peripherals (including networking interfaces, if any). Execution is resumed from the main script, just as with a reset. The reset cause can be checked to know that we are coming from machine.DEEPSLEEP. For wake up to actually happen, wake sources should be configured first, like Pin change or RTC timeout.

Miscellaneous functions

machine.unique_id()
Returns a byte string with a unique identifier of a board/SoC. It will vary from a board/SoC instance to another, if underlying hardware allows. Length varies by hardware (so use substring of a full value if you expect a short ID). In some MicroPython ports, ID corresponds to the network MAC address.

machine.time_pulse_us(pin, pulse_level, timeout_us=1000000)
Time a pulse on the given pin, and return the duration of the pulse in microseconds. The pulse_level argument should be 0 to time a low pulse or 1 to time a high pulse.

If the current input value of the pin is different to pulse_level, the function first (*) waits until the pin input becomes equal to pulse_level, then (**) times the duration that the pin is equal to pulse_level. If the pin is already equal to pulse_level then timing starts straight away.

The function will return -2 if there was timeout waiting for condition marked (*) above, and -1 if there was timeout during the main measurement, marked (**) above. The timeout is the same for both cases and given by timeout_us (which is in microseconds).

Constants

machine.IDLE
machine.SLEEP
machine.DEEPSLEEP
  IRQ wake values.

machine.PWRON_RESET
machine.HARD_RESET
machine.WDT_RESET
machine.DEEPSLEEP_RESET
machine.SOF reset
  Reset causes.

machine.WLAN_WAKE
machine.PIN_WAKE
machine.RTC_WAKE
  Wake-up reasons.

Classes
class Pin – control I/O pins

A pin object is used to control I/O pins (also known as GPIO - general-purpose input/output). Pin objects are commonly associated with a physical pin that can drive an output voltage and read input voltages. The pin class has methods to set the mode of the pin (IN, OUT, etc) and methods to get and set the digital logic level. For analog control of a pin, see the ADC class.

A pin object is constructed by using an identifier which unambiguously specifies a certain I/O pin. The allowed forms of the identifier and the physical pin that the identifier maps to are port-specific. Possibilities for the identifier are an integer, a string or a tuple with port and pin number.

Usage Model:

```python
from machine import Pin

# create an output pin on pin #0
p0 = Pin(0, Pin.OUT)

# set the value low then high
p0.value(0)
p0.value(1)

# create an input pin on pin #2, with a pull up resistor
p2 = Pin(2, Pin.IN, Pin.PULL_UP)

# read and print the pin value
print(p2.value())

# reconfigure pin #0 in input mode
p0.mode(p0.IN)

# configure an irq callback
p0.irq(lambda p:print(p))
```

Constructors

```python
class machine.Pin(id, mode=-1, pull=-1, *, value, drive, alt)
```

Access the pin peripheral (GPIO pin) associated with the given id. If additional arguments are given in the constructor then they are used to initialise the pin. Any settings that are not specified will remain in their previous state.

The arguments are:

- *id* is mandatory and can be an arbitrary object. Among possible value types are: int (an internal Pin identifier), str (a Pin name), and tuple (pair of [port, pin]).
- *mode* specifies the pin mode, which can be one of:
  - `Pin.IN` - Pin is configured for input. If viewed as an output the pin is in high-impedance state.
  - `Pin.OUT` - Pin is configured for (normal) output.
  - `Pin.OPEN_DRAIN` - Pin is configured for open-drain output. Open-drain output works in the following way: if the output value is set to 0 the pin is active at a low level; if the output value is 1 the pin is in a high-impedance state. Not all ports implement this mode, or some might only on certain pins.
- **Pin.ALT** - Pin is configured to perform an alternative function, which is port specific. For a pin configured in such a way any other Pin methods (except `Pin.init()`) are not applicable (calling them will lead to undefined, or a hardware-specific, result). Not all ports implement this mode.

- **Pin.ALT_OPEN_DRAIN** - The same as Pin.ALT, but the pin is configured as open-drain. Not all ports implement this mode.

**• pull** specifies if the pin has a (weak) pull resistor attached, and can be one of:
  - **None** - No pull up or down resistor.
  - **Pin.PULL_UP** - Pull up resistor enabled.
  - **Pin.PULL_DOWN** - Pull down resistor enabled.

**• value** is valid only for Pin.OUT and Pin.OPEN_DRAIN modes and specifies initial output pin value if given, otherwise the state of the pin peripheral remains unchanged.

**• drive** specifies the output power of the pin and can be one of: Pin.LOW_POWER, Pin.MED_POWER or Pin.HIGH_POWER. The actual current driving capabilities are port dependent. Not all ports implement this argument.

**• alt** specifies an alternate function for the pin and the values it can take are port dependent. This argument is valid only for Pin.ALT and Pin.ALT_OPEN_DRAIN modes. It may be used when a pin supports more than one alternate function. If only one pin alternate function is supported the this argument is not required. Not all ports implement this argument.

As specified above, the Pin class allows to set an alternate function for a particular pin, but it does not specify any further operations on such a pin. Pins configured in alternate-function mode are usually not used as GPIO but are instead driven by other hardware peripherals. The only operation supported on such a pin is re-initialising, by calling the constructor or `Pin.init()` method. If a pin that is configured in alternate-function mode is re-initialised with `Pin.IN`, `Pin.OUT`, or `Pin.OPEN_DRAIN`, the alternate function will be removed from the pin.

**Methods**

`Pin.init(mode=-1, pull=-1, *, value, drive, alt)`

Re-initialise the pin using the given parameters. Only those arguments that are specified will be set. The rest of the pin peripheral state will remain unchanged. See the constructor documentation for details of the arguments.

Returns None.

`Pin.value([x])`

This method allows to set and get the value of the pin, depending on whether the argument x is supplied or not.

If the argument is omitted then this method gets the digital logic level of the pin, returning 0 or 1 corresponding to low and high voltage signals respectively. The behaviour of this method depends on the mode of the pin:

- **Pin.IN** - The method returns the actual input value currently present on the pin.
- **Pin.OUT** - The behaviour and return value of the method is undefined.
- **Pin.OPEN_DRAIN** - If the pin is in state ‘0’ then the behaviour and return value of the method is undefined. Otherwise, if the pin is in state ‘1’, the method returns the actual input value currently present on the pin.

If the argument is supplied then this method sets the digital logic level of the pin. The argument x can be anything that converts to a boolean. If it converts to True, the pin is set to state ‘1’, otherwise it is set to state ‘0’. The behaviour of this method depends on the mode of the pin:
• **Pin.IN** - The value is stored in the output buffer for the pin. The pin state does not change, it remains in the high-impedance state. The stored value will become active on the pin as soon as it is changed to **Pin.OUT** or **Pin.OPEN_DRAIN** mode.

• **Pin.OUT** - The output buffer is set to the given value immediately.

• **Pin.OPEN_DRAIN** - If the value is ‘0’ the pin is set to a low voltage state. Otherwise the pin is set to high-impedance state.

When setting the value this method returns *None*.

```
Pin.__call__(x)
```

Pin objects are callable. The call method provides a (fast) shortcut to set and get the value of the pin. It is equivalent to `Pin.value([x])`. See `Pin.value()` for more details.

```
Pin.on()
Set pin to “1” output level.
```

```
Pin.off()
Set pin to “0” output level.
```

```
Pin.mode([mode])
Get or set the pin mode. See the constructor documentation for details of the mode argument.
```

```
Pin.pull([pull])
Get or set the pin pull state. See the constructor documentation for details of the pull argument.
```

```
Pin.drive([drive])
Get or set the pin drive strength. See the constructor documentation for details of the drive argument.
```

Not all ports implement this method.

Availability: WiPy.

```
Pin.irq(handler=None, trigger=(Pin.IRQ_FALLING | Pin.IRQ_RISING), *, priority=1, wake=None)
```

Configure an interrupt handler to be called when the trigger source of the pin is active. If the pin mode is **Pin.IN** then the trigger source is the external value on the pin. If the pin mode is **Pin.OUT** then the trigger source is the output buffer of the pin. Otherwise, if the pin mode is **Pin.OPEN_DRAIN** then the trigger source is the output buffer for state ‘0’ and the external pin value for state ‘1’.

The arguments are:

• **handler** is an optional function to be called when the interrupt triggers.

• **trigger** configures the event which can generate an interrupt. Possible values are:
  - **Pin IRQ_FALLING** interrupt on falling edge.
  - **Pin IRQ_RISING** interrupt on rising edge.
  - **Pin IRQ_LOW_LEVEL** interrupt on low level.
  - **Pin IRQ_HIGH_LEVEL** interrupt on high level.

These values can be OR’ed together to trigger on multiple events.

• **priority** sets the priority level of the interrupt. The values it can take are port-specific, but higher values always represent higher priorities.

• **wake** selects the power mode in which this interrupt can wake up the system. It can be `machine.IDLE`, `machine.SLEEP` or `machine.DEEPSLEEP`. These values can also be OR’ed together to make a pin generate interrupts in more than one power mode.

This method returns a callback object.
Constants

The following constants are used to configure the pin objects. Note that not all constants are available on all ports.

- **Pin.IN**
- **Pin.OUT**
- **Pin.OPEN_DRAIN**
- **Pin.ALT**
- **Pin.ALT_OPEN_DRAIN**
  - Selects the pin mode.
- **Pin.PULL_UP**
- **Pin.PULL_DOWN**
  - Selects whether there is a pull up/down resistor. Use the value `None` for no pull.
- **Pin.LOW_POWER**
- **Pin.MED_POWER**
- **Pin.HIGH_POWER**
  - Selects the pin drive strength.
- **PinIRQ_FALLING**
- **Pin IRQ_RISING**
- **Pin IRQ_LOW_LEVEL**
- **Pin IRQ_HIGH_LEVEL**
  - Selects the IRQ trigger type.

**class Signal – control and sense external I/O devices**

The Signal class is a simple extension of the `Pin` class. Unlike Pin, which can be only in “absolute” 0 and 1 states, a Signal can be in “asserted” (on) or “deasserted” (off) states, while being inverted (active-low) or not. In other words, it adds logical inversion support to Pin functionality. While this may seem a simple addition, it is exactly what is needed to support wide array of simple digital devices in a way portable across different boards, which is one of the major MicroPython goals. Regardless of whether different users have an active-high or active-low LED, a normally open or normally closed relay - you can develop a single, nicely looking application which works with each of them, and capture hardware configuration differences in few lines in the config file of your app.

Example:

```python
from machine import Pin, Signal

# Suppose you have an active-high LED on pin 0
led1_pin = Pin(0, Pin.OUT)
# ... and active-low LED on pin 1
led2_pin = Pin(1, Pin.OUT)

# Now to light up both of them using Pin class, you'll need to set
# them to different values
led1_pin.value(1)
led2_pin.value(0)

# Signal class allows to abstract away active-high/active-low
# difference
led1 = Signal(led1_pin, invert=False)
led2 = Signal(led2_pin, invert=True)

# Now lighting up them looks the same
led1.value(1)
```

Chapter 4. MicroPython libraries
led2.value(1)

# Even better:
led1.on()
led2.on()

Following is the guide when Signal vs Pin should be used:

- Use Signal: If you want to control a simple on/off (including software PWM!) devices like LEDs, multi-segment indicators, relays, buzzers, or read simple binary sensors, like normally open or normally closed buttons, pulled high or low, Reed switches, moisture/flame detectors, etc. etc. Summing up, if you have a real physical device/sensor requiring GPIO access, you likely should use a Signal.

- Use Pin: If you implement a higher-level protocol or bus to communicate with more complex devices.

The split between Pin and Signal come from the usecases above and the architecture of MicroPython: Pin offers the lowest overhead, which may be important when bit-banging protocols. But Signal adds additional flexibility on top of Pin, at the cost of minor overhead (much smaller than if you implemented active-high vs active-low device differences in Python manually!). Also, Pin is a low-level object which needs to be implemented for each support board, while Signal is a high-level object which comes for free once Pin is implemented.

If in doubt, give the Signal a try! Once again, it is offered to save developers from the need to handle unexciting differences like active-low vs active-high signals, and allow other users to share and enjoy your application, instead of being frustrated by the fact that it doesn’t work for them simply because their LEDs or relays are wired in a slightly different way.

Constructors

```python
class machine.Signal(pin_obj, invert=False)
class machine.Signal(pin_arguments..., *, invert=False)
```

Create a Signal object. There're two ways to create it:

- By wrapping existing Pin object - universal method which works for any board.
- By passing required Pin parameters directly to Signal constructor, skipping the need to create intermediate Pin object. Available on many, but not all boards.

The arguments are:

- `pin_obj` is existing Pin object.
- `pin_arguments` are the same arguments as can be passed to Pin constructor.
- `invert` - if True, the signal will be inverted (active low).

Methods

```python
Signal.value(x)
```

This method allows to set and get the value of the signal, depending on whether the argument \( x \) is supplied or not.

If the argument is omitted then this method gets the signal level, 1 meaning signal is asserted (active) and 0 - signal inactive.

If the argument is supplied then this method sets the signal level. The argument \( x \) can be anything that converts to a boolean. If it converts to `True`, the signal is active, otherwise it is inactive.
Correspondence between signal being active and actual logic level on the underlying pin depends on whether signal is inverted (active-low) or not. For non-inverted signal, active status corresponds to logical 1, inactive - to logical 0. For inverted/active-low signal, active status corresponds to logical 0, while inactive - to logical 1.

```python
Signal.on()
Activate signal.
```

```python
Signal.off()
Deactivate signal.
```

**class UART – duplex serial communication bus**

UART implements the standard UART/USART duplex serial communications protocol. At the physical level it consists of 2 lines: RX and TX. The unit of communication is a character (not to be confused with a string character) which can be 8 or 9 bits wide.

UART objects can be created and initialised using:

```python
from machine import UART
uart = UART(1, 9600)  # init with given baudrate
uart.init(9600, bits=8, parity=None, stop=1)  # init with given parameters
```

Supported parameters differ on a board:

- **Pyboard:** Bits can be 7, 8 or 9. Stop can be 1 or 2. With `parity=None`, only 8 and 9 bits are supported. With parity enabled, only 7 and 8 bits are supported.
- **WiPy/CC3200:** Bits can be 5, 6, 7, 8. Stop can be 1 or 2.

A UART object acts like a `stream` object and reading and writing is done using the standard stream methods:

```python
uart.read(10)  # read 10 characters, returns a bytes object
uart.read()  # read all available characters
uart.readline()  # read a line
uart.readinto(buf)  # read and store into the given buffer
uart.write('abc')  # write the 3 characters
```

### Constructors

```python
class machine.UART(id, ...)
Construct a UART object of the given id.
```

### Methods

UART.deinit()  
Turn off the UART bus.

UART.any()  
Returns an integer counting the number of characters that can be read without blocking. It will return 0 if there are no characters available and a positive number if there are characters. The method may return 1 even if there is more than one character available for reading.

For more sophisticated querying of available characters use `select.poll`:  

72 Chapter 4. MicroPython libraries
poll = select.poll()
poll.register(uart, select.POLLIN)
poll.poll(timeout)

UART.read([nbytes])
Read characters. If nbytes is specified then read at most that many bytes, otherwise read as much data as
possible.

Return value: a bytes object containing the bytes read in. Returns None on timeout.

UART.readinto(buf[, nbytes])
Read bytes into the buf. If nbytes is specified then read at most that many bytes. Otherwise, read at most
len(buf) bytes.

Return value: number of bytes read and stored into buf or None on timeout.

UART.readline()
Read a line, ending in a newline character.

Return value: the line read or None on timeout.

UART.write(buf)
Write the buffer of bytes to the bus.

Return value: number of bytes written or None on timeout.

UART.sendbreak()
Send a break condition on the bus. This drives the bus low for a duration longer than required for a normal
transmission of a character.

class SPI – a Serial Peripheral Interface bus protocol (master side)

SPI is a synchronous serial protocol that is driven by a master. At the physical level, a bus consists of 3 lines: SCK,
MOSI, MISO. Multiple devices can share the same bus. Each device should have a separate, 4th signal, SS (Slave
Select), to select a particular device on a bus with which communication takes place. Management of an SS signal
should happen in user code (via machine.Pin class).

Constructors

class machine.SPI(id, ...)
Construct an SPI object on the given bus, id. Values of id depend on a particular port and its hardware. Values
0, 1, etc. are commonly used to select hardware SPI block #0, #1, etc. Value -1 can be used for bitbanging
software implementation of SPI (if supported by a port).

With no additional parameters, the SPI object is created but not initialised (it has the settings from the last
initialisation of the bus, if any). If extra arguments are given, the bus is initialised. See init for parameters of
initialisation.

Methods

SPI.init(baudrate=1000000, *, polarity=0, phase=0, bits=8, firstbit=SPI.MSB, sck=None, mosi=None,
          miso=None, pins=(SCK, MOSI, MISO))
Initialise the SPI bus with the given parameters:
  • baudrate is the SCK clock rate.

4.2. MicroPython-specific libraries
- polarity can be 0 or 1, and is the level the idle clock line sits at.
- phase can be 0 or 1 to sample data on the first or second clock edge respectively.
- bits is the width in bits of each transfer. Only 8 is guaranteed to be supported by all hardware.
- firstbit can be SPI.MSB or SPI.LSB.
- sck, mosi, miso are pins (machine.Pin) objects to use for bus signals. For most hardware SPI blocks (as selected by id parameter to the constructor), pins are fixed and cannot be changed. In some cases, hardware blocks allow 2-3 alternative pin sets for a hardware SPI block. Arbitrary pin assignments are possible only for a bitbanging SPI driver (id = -1).
- pins - WiPy port doesn’t sck, mosi, miso arguments, and instead allows to specify them as a tuple of pins parameter.

**SPI.deinit()**
Turn off the SPI bus.

**SPI.read(nbytes, write=0x00)**
Read a number of bytes specified by nbytes while continuously writing the single byte given by write. Returns a bytes object with the data that was read.

**SPI.readinto(buf, write=0x00)**
Read into the buffer specified by buf while continuously writing the single byte given by write. Returns None.

Note: on WiPy this function returns the number of bytes read.

**SPI.write(buf)**
Write the bytes contained in buf. Returns None.

Note: on WiPy this function returns the number of bytes written.

**SPI.write_readinto(write_buf, read_buf)**
Write the bytes from write_buf while reading into read_buf. The buffers can be the same or different, but both buffers must have the same length. Returns None.

Note: on WiPy this function returns the number of bytes written.

### Constants

**SPI.MASTER**
for initialising the SPI bus to master; this is only used for the WiPy

**SPI.MSB**
set the first bit to be the most significant bit

**SPI.LSB**
set the first bit to be the least significant bit

### class I2C – a two-wire serial protocol

I2C is a two-wire protocol for communicating between devices. At the physical level it consists of 2 wires: SCL and SDA, the clock and data lines respectively.

I2C objects are created attached to a specific bus. They can be initialised when created, or initialised later on.

Printing the I2C object gives you information about its configuration.

Example usage:
```python
from machine import I2C

i2c = I2C(freq=400000)  # create I2C peripheral at frequency of 400kHz
                         # depending on the port, extra parameters may be
                         # to select the peripheral and/or pins to use
i2c.scan()               # scan for slaves, returning a list of 7-bit addresses

i2c.writeto(42, b'123')  # write 3 bytes to slave with 7-bit address 42
i2c.readfrom(42, 4)      # read 4 bytes from slave with 7-bit address 42

i2c.readfrom_mem(42, 8, 3)  # read 3 bytes from memory of slave 42,
                           # starting at memory-address 8 in the slave
i2c.writeto_mem(42, 2, b'\x10')  # write 1 byte to memory of slave 42
                                # starting at address 2 in the slave
```

### Constructors

```python
class machine.I2C(id=-1, *, scl, sda, freq=400000)
```

Construct and return a new I2C object using the following parameters:

- `id` identifies a particular I2C peripheral. The default value of -1 selects a software implementation of I2C which can work (in most cases) with arbitrary pins for SCL and SDA. If `id` is -1 then `scl` and `sda` must be specified. Other allowed values for `id` depend on the particular port/board, and specifying `scl` and `sda` may or may not be required or allowed in this case.

- `scl` should be a pin object specifying the pin to use for SCL.

- `sda` should be a pin object specifying the pin to use for SDA.

- `freq` should be an integer which sets the maximum frequency for SCL.

### General Methods

```python
I2C.init(scl, sda, *, freq=400000)
```

Initialise the I2C bus with the given arguments:

- `scl` is a pin object for the SCL line
- `sda` is a pin object for the SDA line
- `freq` is the SCL clock rate

```python
I2C.deinit()
```

Turn off the I2C bus.

Availability: WiPy.

```python
I2C.scan()
```

Scan all I2C addresses between 0x08 and 0x77 inclusive and return a list of those that respond. A device responds if it pulls the SDA line low after its address (including a write bit) is sent on the bus.
**Primitive I2C operations**

The following methods implement the primitive I2C master bus operations and can be combined to make any I2C transaction. They are provided if you need more control over the bus, otherwise the standard methods (see below) can be used.

```python
I2C.start()
```
Generate a START condition on the bus (SDA transitions to low while SCL is high).

Availability: ESP8266.

```python
I2C.stop()
```
Generate a STOP condition on the bus (SDA transitions to high while SCL is high).

Availability: ESP8266.

```python
I2C.readinto(buf, nack=True)
```
Reads bytes from the bus and stores them into `buf`. The number of bytes read is the length of `buf`. An ACK will be sent on the bus after receiving all but the last byte. After the last byte is received, if `nack` is true then a NACK will be sent, otherwise an ACK will be sent (and in this case the slave assumes more bytes are going to be read in a later call).

Availability: ESP8266.

```python
I2C.write(buf)
```
Write the bytes from `buf` to the bus. Checks that an ACK is received after each byte and stops transmitting the remaining bytes if a NACK is received. The function returns the number of ACKs that were received.

Availability: ESP8266.

**Standard bus operations**

The following methods implement the standard I2C master read and write operations that target a given slave device.

```python
I2C.readfrom(addr, nbytes, stop=True)
```
Read `nbytes` from the slave specified by `addr`. If `stop` is true then a STOP condition is generated at the end of the transfer. Returns a `bytes` object with the data read.

```python
I2C.readfrom_into(addr, buf, stop=True)
```
Read into `buf` from the slave specified by `addr`. The number of bytes read will be the length of `buf`. If `stop` is true then a STOP condition is generated at the end of the transfer.

The method returns `None`.

```python
I2C.writeto(addr, buf, stop=True)
```
Write the bytes from `buf` to the slave specified by `addr`. If a NACK is received following the write of a byte from `buf` then the remaining bytes are not sent. If `stop` is true then a STOP condition is generated at the end of the transfer, even if a NACK is received. The function returns the number of ACKs that were received.

**Memory operations**

Some I2C devices act as a memory device (or set of registers) that can be read from and written to. In this case there are two addresses associated with an I2C transaction: the slave address and the memory address. The following methods are convenience functions to communicate with such devices.

```python
I2C.readfrom_mem(addr, memaddr, nbytes, *, addrsize=8)
```
Read `nbytes` from the slave specified by `addr` starting from the memory address specified by `memaddr`. The argument `addrsize` specifies the address size in bits. Returns a `bytes` object with the data read.
I2C.*readfrom_mem_into*(addr, memaddr, buf, *, addrsize=8*)
Read into buf from the slave specified by addr starting from the memory address specified by memaddr. The number of bytes read is the length of buf. The argument addrsize specifies the address size in bits (on ESP8266 this argument is not recognised and the address size is always 8 bits).

The method returns None.

I2C.*writeto_mem*(addr, memaddr, buf, *, addrsize=8*)
Write buf to the slave specified by addr starting from the memory address specified by memaddr. The argument addrsize specifies the address size in bits (on ESP8266 this argument is not recognised and the address size is always 8 bits).

The method returns None.

class RTC – real time clock

The RTC is an independent clock that keeps track of the date and time.

Example usage:

```python
rtc = machine.RTC()
rtc.init((2014, 5, 1, 4, 13, 0, 0, 0))
print(rtc.now())
```

Constructors

class machine.RTC(id=0,...)
Create an RTC object. See init for parameters of initialization.

Methods

RTC.*init*(datetime)
Initialise the RTC. Datetime is a tuple of the form:

(year, month, day[, hour[, minute[, second[, microsecond[, tzinfo]]]]])

RTC.*now*()
Get the current datetime tuple.

RTC.*deinit*()
Resets the RTC to the time of January 1, 2015 and starts running it again.

RTC.*alarm*(id, time, *, repeat=False)
Set the RTC alarm. Time might be either a millisecond value to program the alarm to current time + time_in_ms in the future, or a datetimetuple. If the time passed is in milliseconds, repeat can be set to True to make the alarm periodic.

RTC.*alarm_left*(alarm_id=0)
Get the number of milliseconds left before the alarm expires.

RTC.*cancel*(alarm_id=0)
Cancel a running alarm.

RTC.*irq*(*, trigger, handler=None, wake=machine.IDLE)
Create an irq object triggered by a real time clock alarm.

4.2. MicroPython-specific libraries
• trigger must be RTC.ALARM0
• handler is the function to be called when the callback is triggered.
• wake specifies the sleep mode from where this interrupt can wake up the system.

Constants

RTC.ALARM0
  irq trigger source

class Timer – control hardware timers

Hardware timers deal with timing of periods and events. Timers are perhaps the most flexible and heterogeneous kind of hardware in MCUs and SoCs, differently greatly from a model to a model. MicroPython’s Timer class defines a baseline operation of executing a callback with a given period (or once after some delay), and allow specific boards to define more non-standard behavior (which thus won’t be portable to other boards).

See discussion of important constraints on Timer callbacks.

Note: Memory can’t be allocated inside irq handlers (an interrupt) and so exceptions raised within a handler don’t give much information. See `micropython.alloc_emergency_exception_buf()` for how to get around this limitation.

Constructors

class `machine.Timer(id, ...)`
  Construct a new timer object of the given id. Id of -1 constructs a virtual timer (if supported by a board).

Methods

`Timer.deinit()`
  Deinitialises the timer. Stops the timer, and disables the timer peripheral.

Constants

`Timer.ONE_SHOT`
`Timer.PERIODIC`
  Timer operating mode.

class WDT – watchdog timer

The WDT is used to restart the system when the application crashes and ends up into a non recoverable state. Once started it cannot be stopped or reconfigured in any way. After enabling, the application must “feed” the watchdog periodically to prevent it from expiring and resetting the system.

Example usage:
from machine import WDT
wdt = WDT(timeout=2000)  # enable it with a timeout of 2s
wdt.feed()

Availability of this class: pyboard, WiPy.

Constructors

class machine.WDT(id=0, timeout=5000)

Create a WDT object and start it. The timeout must be given in seconds and the minimum value that is accepted is 1 second. Once it is running the timeout cannot be changed and the WDT cannot be stopped either.

Methods

wdt.feed()

Feed the WDT to prevent it from resetting the system. The application should place this call in a sensible place ensuring that the WDT is only fed after verifying that everything is functioning correctly.

4.2.4 micropython – access and control MicroPython internals

Functions

micropython.const(expr)

Used to declare that the expression is a constant so that the compile can optimise it. The use of this function should be as follows:

```python
from micropython import const

CONST_X = const(123)
CONST_Y = const(2 * CONST_X + 1)
```

Constants declared this way are still accessible as global variables from outside the module they are declared in. On the other hand, if a constant begins with an underscore then it is hidden, it is not available as a global variable, and does not take up any memory during execution.

This `const` function is recognised directly by the MicroPython parser and is provided as part of the `micropython` module mainly so that scripts can be written which run under both CPython and MicroPython, by following the above pattern.

micropython.opt_level([level])

If `level` is given then this function sets the optimisation level for subsequent compilation of scripts, and returns None. Otherwise it returns the current optimisation level.

The optimisation level controls the following compilation features:

- Assertions: at level 0 assertion statements are enabled and compiled into the bytecode; at levels 1 and higher assertions are not compiled.
- Built-in `__debug__` variable: at level 0 this variable expands to `True`; at levels 1 and higher it expands to `False`.
- Source-code line numbers: at levels 0, 1 and 2 source-code line number are stored along with the bytecode so that exceptions can report the line number they occurred at; at levels 3 and higher line numbers are not stored.
The default optimisation level is usually level 0.

**micropython.alloc_emergency_exception_buf(size)**

Allocate size bytes of RAM for the emergency exception buffer (a good size is around 100 bytes). The buffer is used to create exceptions in cases when normal RAM allocation would fail (eg within an interrupt handler) and therefore give useful traceback information in these situations.

A good way to use this function is to put it at the start of your main script (eg boot.py or main.py) and then the emergency exception buffer will be active for all the code following it.

**micropython.mem_info([verbose])**

Print information about currently used memory. If the verbose argument is given then extra information is printed.

The information that is printed is implementation dependent, but currently includes the amount of stack and heap used. In verbose mode it prints out the entire heap indicating which blocks are used and which are free.

**micropython.qstr_info([verbose])**

Print information about currently interned strings. If the verbose argument is given then extra information is printed.

The information that is printed is implementation dependent, but currently includes the number of interned strings and the amount of RAM they use. In verbose mode it prints out the names of all RAM-interned strings.

**micropython.stack_use()**

Return an integer representing the current amount of stack that is being used. The absolute value of this is not particularly useful, rather it should be used to compute differences in stack usage at different points.

**micropython.heap_lock()**

**micropython.heap_unlock()**

Lock or unlock the heap. When locked no memory allocation can occur and a *MemoryError* will be raised if any heap allocation is attempted.

These functions can be nested, ie *heap_lock()* can be called multiple times in a row and the lock-depth will increase, and then *heap_unlock()* must be called the same number of times to make the heap available again.

**micropython.kbd_intr(chr)**

Set the character that will raise a *KeyboardInterrupt* exception. By default this is set to 3 during script execution, corresponding to Ctrl-C. Passing -1 to this function will disable capture of Ctrl-C, and passing 3 will restore it.

This function can be used to prevent the capturing of Ctrl-C on the incoming stream of characters that is usually used for the REPL, in case that stream is used for other purposes.

**micropython.schedule(func, arg)**

Schedule the function *func* to be executed “very soon”. The function is passed the value *arg* as its single argument. “Very soon” means that the MicroPython runtime will do its best to execute the function at the earliest possible time, given that it is also trying to be efficient, and that the following conditions hold:

- A scheduled function will never preempt another scheduled function.
- Scheduled functions are always executed “between opcodes” which means that all fundamental Python operations (such as appending to a list) are guaranteed to be atomic.
- A given port may define “critical regions” within which scheduled functions will never be executed. Functions may be scheduled within a critical region but they will not be executed until that region is exited. An example of a critical region is a preempting interrupt handler (an IRQ).
A use for this function is to schedule a callback from a preempting IRQ. Such an IRQ puts restrictions on the code that runs in the IRQ (for example the heap may be locked) and scheduling a function to call later will lift those restrictions.

Note: If `schedule()` is called from a preempting IRQ, when memory allocation is not allowed and the callback to be passed to `schedule()` is a bound method, passing this directly will fail. This is because creating a reference to a bound method causes memory allocation. A solution is to create a reference to the method in the class constructor and to pass that reference to `schedule()`. This is discussed in detail here under “Creation of Python objects”.

There is a finite stack to hold the scheduled functions and `schedule()` will raise a `RuntimeError` if the stack is full.

### 4.2.5 network — network configuration

This module provides network drivers and routing configuration. To use this module, a MicroPython variant/build with network capabilities must be installed. Network drivers for specific hardware are available within this module and are used to configure hardware network interface(s). Network services provided by configured interfaces are then available for use via the `usocket` module.

For example:

```python
# connect/ show IP config a specific network interface
# see below for examples of specific drivers
import network
import utime
nic = network.Driver(...)  
if not nic.isconnected():
    nic.connect()
    print("Waiting for connection...")
    while not nic.isconnected():
        utime.sleep(1)
    print(nic.ifconfig())

# now use usocket as usual
import usocket as socket
addr = socket.getaddrinfo('micropython.org', 80)[0][-1]
s = socket.socket()
s.connect(addr)
s.send(b'GET / HTTP/1.1\r\nHost: micropython.org\r\n\r
')
data = s.recv(1000)
s.close()
```

#### Common network adapter interface

This section describes an (implied) abstract base class for all network interface classes implemented by MicroPython ports for different hardware. This means that MicroPython does not actually provide AbstractNIC class, but any actual NIC class, as described in the following sections, implements methods as described here.

```python
class network.AbstractNIC(id=None, ...)
```

Instantiate a network interface object. Parameters are network interface dependent. If there are more than one interface of the same type, the first parameter should be `id`.

4.2. MicroPython-specific libraries 81
network.active([is_active])
Activate ("up") or deactivate ("down") the network interface, if a boolean argument is passed. Otherwise, query current state if no argument is provided. Most other methods require an active interface (behavior of calling them on inactive interface is undefined).

network.connect([service_id, key=None, *,...])
Connect the interface to a network. This method is optional, and available only for interfaces which are not "always connected". If no parameters are given, connect to the default (or the only) service. If a single parameter is given, it is the primary identifier of a service to connect to. It may be accompanied by a key (password) required to access said service. There can be further arbitrary keyword-only parameters, depending on the networking medium type and/or particular device. Parameters can be used to: a) specify alternative service identifier types; b) provide additional connection parameters. For various medium types, there are different sets of predefined/recommended parameters, among them:

- WiFi: bssid keyword to connect to a specific BSSID (MAC address)

network.disconnect()
Disconnect from network.

network.isconnected()
Returns True if connected to network, otherwise returns False.

network.scan(*,...)
Scan for the available network services/connections. Returns a list of tuples with discovered service parameters. For various network media, there are different variants of predefined/recommended tuple formats, among them:

- WiFi: (ssid, bssid, channel, RSSI, authmode, hidden). There may be further fields, specific to a particular device.

The function may accept additional keyword arguments to filter scan results (e.g. scan for a particular service, on a particular channel, for services of a particular set, etc.), and to affect scan duration and other parameters. Where possible, parameter names should match those in connect().

network.status([param])
Query dynamic status information of the interface. When called with no argument the return value describes the network link status. Otherwise param should be a string naming the particular status parameter to retrieve.

The return types and values are dependent on the network medium/technology. Some of the parameters that may be supported are:

- WiFi STA: use 'rssi' to retrieve the RSSI of the AP signal
- WiFi AP: use 'stations' to retrieve a list of all the STAs connected to the AP. The list contains tuples of the form (MAC, RSSI).

network.ifconfig([('ip, subnet, gateway, dns)])
Get/set IP-level network interface parameters: IP address, subnet mask, gateway and DNS server. When called with no arguments, this method returns a 4-tuple with the above information. To set the above values, pass a 4-tuple with the required information. For example:

```
nic.ifconfig(('192.168.0.4', '255.255.255.0', '192.168.0.1', '8.8.8.8'))
```

network.config('param')
network.config(param=value, ...)
Get or set general network interface parameters. These methods allow to work with additional parameters beyond standard IP configuration (as dealt with by ifconfig()). These include network-specific and hardware-specific parameters. For setting parameters, the keyword argument syntax
should be used, and multiple parameters can be set at once. For querying, a parameter name should be quoted as a string, and only one parameter can be queried at a time:

```python
# Set WiFi access point name (formally known as ESSID) and WiFi channel
ap.config(essid='My AP', channel=11)
# Query params one by one
print(ap.config('essid'))
print(ap.config('channel'))
```

### Functions

**network.phy_mode**([`mode`])

Get or set the PHY mode.

If the `mode` parameter is provided, sets the mode to its value. If the function is called without parameters, returns the current mode.

**The possible modes are defined as constants:**

- **MODE_11B** – IEEE 802.11b,
- **MODE_11G** – IEEE 802.11g,
- **MODE_11N** – IEEE 802.11n.

### class WLAN

This class provides a driver for WiFi network processor in the ESP8266. Example usage:

```python
import network
# enable station interface and connect to WiFi access point
nic = network.WLAN(network.STA_IF)
nic.active(True)
nic.connect('your-ssid', 'your-password')
# now use sockets as usual
```

### Constructors

**class network.WLAN**(`interface_id`)

Create a WLAN network interface object. Supported interfaces are `network.STA_IF` (station aka client, connects to upstream WiFi access points) and `network.AP_IF` (access point, allows other WiFi clients to connect). Availability of the methods below depends on interface type. For example, only STA interface may `connect()` to an access point.

### Methods

**wlan.active**([`is_active`])

Activate (“up”) or deactivate (“down”) network interface, if boolean argument is passed. Otherwise, query current state if no argument is provided. Most other methods require active interface.

**wlan.connect**(`ssid=None, password=None, *, bssid=None`)

Connect to the specified wireless network, using the specified password. If `bssid` is given then the connection will be restricted to the access-point with that MAC address (the `ssid` must also be specified in this case).
wlan.\texttt{disconnect}()  
Disconnect from the currently connected wireless network.

wlan.\texttt{scan}()  
Scan for the available wireless networks.

Scanning is only possible on STA interface. Returns list of tuples with the information about WiFi access points:

\begin{verbatim}
(ssid, bssid, channel, RSSI, authmode, hidden)
\end{verbatim}

\textit{bssid} is hardware address of an access point, in binary form, returned as bytes object. You can use \texttt{ubinascii.hexlify()} to convert it to ASCII form.

There are five values for authmode:

- 0 – open
- 1 – WEP
- 2 – WPA-PSK
- 3 – WPA2-PSK
- 4 – WPA/WPA2-PSK

and two for hidden:

- 0 – visible
- 1 – hidden

\texttt{wlan.status([param])}  
Return the current status of the wireless connection.

When called with no argument the return value describes the network link status. The possible statuses are defined as constants:

- \texttt{STAT_IDLE} – no connection and no activity,
- \texttt{STAT_CONNECTING} – connecting in progress,
- \texttt{STAT_WRONG_PASSWORD} – failed due to incorrect password,
- \texttt{STAT_NO_AP_FOUND} – failed because no access point replied,
- \texttt{STAT_CONNECT_FAIL} – failed due to other problems,
- \texttt{STAT_GOT_IP} – connection successful.

When called with one argument \textit{param} should be a string naming the status parameter to retrieve. Supported parameters in WiFi STA mode are: \texttt{rssi}.

\texttt{wlan.isconnected()}  
In case of STA mode, returns \texttt{True} if connected to a WiFi access point and has a valid IP address. In AP mode returns \texttt{True} when a station is connected. Returns \texttt{False} otherwise.

\texttt{wlan.ifconfig([ip, subnet, gateway, dns])}  
Get/set IP-level network interface parameters: IP address, subnet mask, gateway and DNS server. When called with no arguments, this method returns a 4-tuple with the above information. To set the above values, pass a 4-tuple with the required information. For example:

\begin{verbatim}
nic.ifconfig(('192.168.0.4', '255.255.255.0', '192.168.0.1', '8.8.8.8'))
\end{verbatim}

\texttt{wlan.config('param')}
wlan.config(param=value,...)

Get or set general network interface parameters. These methods allow to work with additional parameters beyond standard IP configuration (as dealt with by wlan.ifconfig()). These include network-specific and hardware-specific parameters. For setting parameters, keyword argument syntax should be used, multiple parameters can be set at once. For querying, parameters name should be quoted as a string, and only one parameter can be queries at time:

```
# Set WiFi access point name (formally known as ESSID) and WiFi channel
ap.config(essid='My AP', channel=11)
# Query params one by one
print(ap.config('essid'))
print(ap.config('channel'))
```

Following are commonly supported parameters (availability of a specific parameter depends on network technology type, driver, and MicroPython port).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mac</td>
<td>MAC address (bytes)</td>
</tr>
<tr>
<td>essid</td>
<td>WiFi access point name (string)</td>
</tr>
<tr>
<td>channel</td>
<td>WiFi channel (integer)</td>
</tr>
<tr>
<td>hidden</td>
<td>Whether ESSID is hidden (boolean)</td>
</tr>
<tr>
<td>authmode</td>
<td>Authentication mode supported (enumeration, see module constants)</td>
</tr>
<tr>
<td>password</td>
<td>Access password (string)</td>
</tr>
<tr>
<td>dhcp_hostname</td>
<td>The DHCP hostname to use</td>
</tr>
</tbody>
</table>

4.2.6 uctypes – access binary data in a structured way

This module implements “foreign data interface” for MicroPython. The idea behind it is similar to CPython’s ctypes modules, but the actual API is different, streamlined and optimized for small size. The basic idea of the module is to define data structure layout with about the same power as the C language allows, and then access it using familiar dot-syntax to reference sub-fields.

See also:

Module ustruct Standard Python way to access binary data structures (doesn’t scale well to large and complex structures).

Defining structure layout

Structure layout is defined by a “descriptor” - a Python dictionary which encodes field names as keys and other properties required to access them as associated values. Currently, uctypes requires explicit specification of offsets for each field. Offset are given in bytes from a structure start.

Following are encoding examples for various field types:

- Scalar types:

  ```python
  "field_name": offset | uctypes.UINT32
  ```

  in other words, value is scalar type identifier ORed with field offset (in bytes) from the start of the structure.

- Recursive structures:

  ```python
  "sub": (offset, {
      "b0": 0 | uctypes.UINT8,
  })
  ```
i.e. value is a 2-tuple, first element of which is offset, and second is a structure descriptor dictionary (note: offsets in recursive descriptors are relative to the structure it defines).

- Arrays of primitive types:

```python
"arr": (offset | uctypes.ARRAY, size | uctypes.UINT8),
```

i.e. value is a 2-tuple, first element of which is ARRAY flag ORed with offset, and second is scalar element type ORed number of elements in array.

- Arrays of aggregate types:

```python
"arr2": (offset | uctypes.ARRAY, size, {"b": 0 | uctypes.UINT8}),
```

i.e. value is a 3-tuple, first element of which is ARRAY flag ORed with offset, second is a number of elements in array, and third is descriptor of element type.

- Pointer to a primitive type:

```python
"ptr": (offset | uctypes.PTR, uctypes.UINT8),
```

i.e. value is a 2-tuple, first element of which is PTR flag ORed with offset, and second is scalar element type.

- Pointer to an aggregate type:

```python
"ptr2": (offset | uctypes.PTR, {"b": 0 | uctypes.UINT8}),
```

i.e. value is a 2-tuple, first element of which is PTR flag ORed with offset, second is descriptor of type pointed to.

- Bitfields:

```python
"bitf0": offset | uctypes.BFUINT16 | lsbit << uctypes.BF_POS | bitsize << uctypes.BF_LEN,
```

i.e. value is type of scalar value containing given bitfield (typenames are similar to scalar types, but prefixes with “BF”), ORed with offset for scalar value containing the bitfield, and further ORed with values for bit offset and bit length of the bitfield within scalar value, shifted by BF_POS and BF_LEN positions, respectively. Bitfield position is counted from the least significant bit, and is the number of right-most bit of a field (in other words, it’s a number of bits a scalar needs to be shifted right to extract the bitfield).

In the example above, first a UINT16 value will be extracted at offset 0 (this detail may be important when accessing hardware registers, where particular access size and alignment are required), and then bitfield whose rightmost bit is \( lsb \) bit of this UINT16, and length is \( bitsize \) bits, will be extracted. For example, if \( lsb \) is 0 and \( bitsize \) is 8, then effectively it will access least-significant byte of UINT16.

Note that bitfield operations are independent of target byte endianness, in particular, example above will access least-significant byte of UINT16 in both little- and big-endian structures. But it depends on the least significant bit being numbered 0. Some targets may use different numbering in their native ABI, but uctypes always uses the normalized numbering described above.

Module contents

```python
class uctypes.struct (addr, descriptor, layout_type=NATIVE)
```

Instantiate a “foreign data structure” object based on structure address in memory, descriptor (encoded as a
dictionary), and layout type (see below).

**uctypes.LITTLE_ENDIAN**
Layout type for a little-endian packed structure. (Packed means that every field occupies exactly as many bytes as defined in the descriptor, i.e. the alignment is 1).

**uctypes.BIG_ENDIAN**
Layout type for a big-endian packed structure.

**uctypes.NATIVE**
Layout type for a native structure - with data endianness and alignment conforming to the ABI of the system on which MicroPython runs.

**uctypes.sizeof(struct)**
Return size of data structure in bytes. Argument can be either structure class or specific instantiated structure object (or its aggregate field).

**uctypes.addressof(obj)**
Return address of an object. Argument should be bytes, bytearray or other object supporting buffer protocol (and address of this buffer is what actually returned).

**uctypes.bytes_at(addr, size)**
Capture memory at the given address and size as bytes object. As bytes object is immutable, memory is actually duplicated and copied into bytes object, so if memory contents change later, created object retains original value.

**uctypes.bytearray_at(addr, size)**
Capture memory at the given address and size as bytearray object. Unlike bytes_at() function above, memory is captured by reference, so it can be both written too, and you will access current value at the given memory address.

Structure descriptors and instantiating structure objects

Given a structure descriptor dictionary and its layout type, you can instantiate a specific structure instance at a given memory address using `uctypes.struct()` constructor. Memory address usually comes from following sources:

- Predefined address, when accessing hardware registers on a baremetal system. Lookup these addresses in datasheet for a particular MCU/SoC.
- As a return value from a call to some FFI (Foreign Function Interface) function.
- From uctypes.addressof(), when you want to pass arguments to an FFI function, or alternatively, to access some data for I/O (for example, data read from a file or network socket).

Structure objects

Structure objects allow accessing individual fields using standard dot notation: `my_struct.substruct1.field1`. If a field is of scalar type, getting it will produce a primitive value (Python integer or float) corresponding to the value contained in a field. A scalar field can also be assigned to.

If a field is an array, its individual elements can be accessed with the standard subscript operator `[]` - both read and assigned to.

If a field is a pointer, it can be dereferenced using `[0]` syntax (corresponding to C `*` operator, though `[0]` works in C too). Subscripting a pointer with other integer values but 0 are supported too, with the same semantics as in C.

Summing up, accessing structure fields generally follows C syntax, except for pointer dereference, when you need to use `[0]` operator instead of `*`. 
Limitations

Accessing non-scalar fields leads to allocation of intermediate objects to represent them. This means that special care should be taken to layout a structure which needs to be accessed when memory allocation is disabled (e.g. from an interrupt). The recommendations are:

- Avoid nested structures. For example, instead of `mcu_registers.peripheral_a.register1`, define separate layout descriptors for each peripheral, to be accessed as `peripheral_a.register1`.
- Avoid other non-scalar data, like array. For example, instead of `peripheral_a.register[0]` use `peripheral_a.register0`.

Note that these recommendations will lead to decreased readability and conciseness of layouts, so they should be used only if the need to access structure fields without allocation is anticipated (it’s even possible to define 2 parallel layouts - one for normal usage, and a restricted one to use when memory allocation is prohibited).

4.3 Libraries specific to the ESP8266

The following libraries are specific to the ESP8266.

4.3.1 esp — functions related to the ESP8266

The `esp` module contains specific functions related to the ESP8266 module.

Functions

```python
esp.sleep_type([sleep_type])
Get or set the sleep type.

If the `sleep_type` parameter is provided, sets the sleep type to its value. If the function is called without parameters, returns the current sleep type.

The possible sleep types are defined as constants:
- SLEEP_NONE – all functions enabled,
- SLEEP_MODEM – modem sleep, shuts down the WiFi Modem circuit.
- SLEEP_LIGHT – light sleep, shuts down the WiFi Modem circuit and suspends the processor periodically.

The system enters the set sleep mode automatically when possible.

esp.deepsleep(time=0)
Enter deep sleep.

The whole module powers down, except for the RTC clock circuit, which can be used to restart the module after the specified time if the pin 16 is connected to the reset pin. Otherwise the module will sleep until manually reset.

esp.flash_id()
Read the device ID of the flash memory.

esp.flash_read(byte_offset, length_or_buffer)

esp.flash_write(byte_offset, bytes)

esp.flash_erase(sector_no)
```
esp.set_native_code_location(start, length)

Set the location that native code will be placed for execution after it is compiled. Native code is emitted when the @micropython.native, @micropython.viper and @micropython.asm_xtensa decorators are applied to a function. The ESP8266 must execute code from either iRAM or the lower 1MByte of flash (which is memory mapped), and this function controls the location.

If start and length are both None then the native code location is set to the unused portion of memory at the end of the iRAM1 region. The size of this unused portion depends on the firmware and is typically quite small (around 500 bytes), and is enough to store a few very small functions. The advantage of using this iRAM1 region is that it does not get worn out by writing to it.

If neither start nor length are None then they should be integers. start should specify the byte offset from the beginning of the flash at which native code should be stored. length specifies how many bytes of flash from start can be used to store native code. start and length should be multiples of the sector size (being 4096 bytes). The flash will be automatically erased before writing to it so be sure to use a region of flash that is not otherwise used, for example by the firmware or the filesystem.

When using the flash to store native code start+length must be less than or equal to 1MByte. Note that the flash can be worn out if repeated erasures (and writes) are made so use this feature sparingly. In particular, native code needs to be recompiled and rewritten to flash on each boot (including wake from deepsleep).

In both cases above, using iRAM1 or flash, if there is no more room left in the specified region then the use of a native decorator on a function will lead to MemoryError exception being raised during compilation of that function.
CHAPTER FIVE

THE MICROPYTHON LANGUAGE

MicroPython aims to implement the Python 3.4 standard (with selected features from later versions) with respect to language syntax, and most of the features of MicroPython are identical to those described by the “Language Reference” documentation at docs.python.org.

The MicroPython standard library is described in the corresponding chapter. The MicroPython differences from CPython chapter describes differences between MicroPython and CPython (which mostly concern standard library and types, but also some language-level features).

This chapter describes features and peculiarities of MicroPython implementation and the best practices to use them.

5.1 Glossary

baremetal A system without a (full-fledged) OS, for example an MCU-based system. When running on a baremetal system, MicroPython effectively becomes its user-facing OS with a command interpreter (REPL).

board A PCB board. Oftentimes, the term is used to denote a particular model of an MCU system. Sometimes, it is used to actually refer to MicroPython port to a particular board (and then may also refer to “boardless” ports like Unix port).

callee-owned tuple A tuple returned by some builtin function/method, containing data which is valid for a limited time, usually until next call to the same function (or a group of related functions). After next call, data in the tuple may be changed. This leads to the following restriction on the usage of callee-owned tuples - references to them cannot be stored. The only valid operation is extracting values from them (including making a copy). Callee-owned tuples is a MicroPython-specific construct (not available in the general Python language), introduced for memory allocation optimization. The idea is that callee-owned tuple is allocated once and stored on the callee side. Subsequent calls don’t require allocation, allowing to return multiple values when allocation is not possible (e.g. in interrupt context) or not desirable (because allocation inherently leads to memory fragmentation). Note that callee-owned tuples are effectively mutable tuples, making an exception to Python’s rule that tuples are immutable. (It may be interesting why tuples were used for such a purpose then, instead of mutable lists - the reason for that is that lists are mutable from user application side too, so a user could do things to a callee-owned list which the callee doesn’t expect and could lead to problems; a tuple is protected from this.)

CPython CPython is the reference implementation of Python programming language, and the most well-known one, which most of the people run. It is however one of many implementations (among which Jython, IronPython, PyPy, and many more, including MicroPython). As there is no formal specification of the Python language, only CPython documentation, it is not always easy to draw a line between Python the language and CPython its particular implementation. This however leaves more freedom for other implementations. For example, MicroPython does a lot of things differently than CPython, while still aspiring to be a Python language implementation.

GPIO General-purpose input/output. The simplest means to control electrical signals. With GPIO, user can configure hardware signal pin to be either input or output, and set or get its digital signal value (logical “0” or “1”). MicroPython abstracts GPIO access using machine.Pin and machine.Signal classes.
**GPIO port** A group of GPIO pins, usually based on hardware properties of these pins (e.g. controllable by the same register).

**Interned string** A string referenced by its (unique) identity rather than its address. Interned strings are thus can be quickly compared just by their identifiers, instead of comparing by content. The drawbacks of interned strings are that interning operation takes time (proportional to the number of existing interned strings, i.e. becoming slower and slower over time) and that the space used for interned strings is not reclaimable. String interning is done automatically by MicroPython compiler and runtimer when it’s either required by the implementation (e.g. function keyword arguments are represented by interned string id’s) or deemed beneficial (e.g. for short enough strings, which have a chance to be repeated, and thus interning them would save memory on copies). Most of string and I/O operations don’t produce interned strings due to drawbacks described above.

**MCU** Microcontroller. Microcontrollers usually have much less resources than a full-fledged computing system, but smaller, cheaper and require much less power. MicroPython is designed to be small and optimized enough to run on an average modern microcontroller.

**Micropython-lib** MicroPython is (usually) distributed as a single executable/binary file with just few builtin modules. There is no extensive standard library comparable with CPython. Instead, there is a related, but separate project micropython-lib which provides implementations for many modules from CPython’s standard library. However, large subset of these modules require POSIX-like environment (Linux, FreeBSD, MacOS, etc.; Windows may be partially supported), and thus would work or make sense only with MicroPython Unix port. Some subset of modules is however usable for baremetal ports too.

Unlike monolithic CPython stdlib, micropython-lib modules are intended to be installed individually - either using manual copying or using upip.

**MicroPython port** MicroPython supports different boards, RTOSes, and OSes, and can be relatively easily adapted to new systems. MicroPython with support for a particular system is called a “port” to that system. Different ports may have widely different functionality. This documentation is intended to be a reference of the generic APIs available across different ports (“MicroPython core”). Note that some ports may still omit some APIs described here (e.g. due to resource constraints). Any such differences, and port-specific extensions beyond MicroPython core functionality, would be described in the separate port-specific documentation.

**MicroPython Unix port** Unix port is one of the major MicroPython ports. It is intended to run on POSIX-compatible operating systems, like Linux, MacOS, FreeBSD, Solaris, etc. It also serves as the basis of Windows port. The importance of Unix port lies in the fact that while there are many different boards, so two random users unlikely have the same board, almost all modern OSes have some level of POSIX compatibility, so Unix port serves as a kind of “common ground” to which any user can have access. So, Unix port is used for initial prototyping, different kinds of testing, development of machine-independent features, etc. All users of MicroPython, even those which are interested only in running MicroPython on MCU systems, are recommended to be familiar with Unix (or Windows) port, as it is important productivity helper and a part of normal MicroPython workflow.

**Port** Either MicroPython port or GPIO port. If not clear from context, it’s recommended to use full specification like one of the above.

**Stream** Also known as a “file-like object”. An object which provides sequential read-write access to the underlying data. A stream object implements a corresponding interface, which consists of methods like read(), write(), readinto(), seek(), flush(), close(), etc. A stream is an important concept in MicroPython, many I/O objects implement the stream interface, and thus can be used consistently and interchangeably in different contexts. For more information on streams in MicroPython, see uio module.

**Upip** (Literally, “micro pip”). A package manager for MicroPython, inspired by CPython’s pip, but much smaller and with reduced functionality. upip runs both on Unix port and on baremetal ports (those which offer filesystem and networking support).
5.2 The MicroPython Interactive Interpreter Mode (aka REPL)

This section covers some characteristics of the MicroPython Interactive Interpreter Mode. A commonly used term for this is REPL (read-eval-print-loop) which will be used to refer to this interactive prompt.

5.2.1 Auto-indent

When typing python statements which end in a colon (for example if, for, while) then the prompt will change to three dots (...) and the cursor will be indented by 4 spaces. When you press return, the next line will continue at the same level of indentation for regular statements or an additional level of indentation where appropriate. If you press the backspace key then it will undo one level of indentation.

If your cursor is all the way back at the beginning, pressing RETURN will then execute the code that you’ve entered. The following shows what you’d see after entering a for statement (the underscore shows where the cursor winds up):

```python
>>> for i in range(30):
... _
```

If you then enter an if statement, an additional level of indentation will be provided:

```python
>>> for i in range(30):
... if i > 3:
... _
```

Now enter `break` followed by RETURN and press BACKSPACE:

```python
>>> for i in range(30):
... if i > 3:
... break
... _
```

Finally type `print(i)`, press RETURN, press BACKSPACE and press RETURN again:

```python
>>> for i in range(30):
... if i > 3:
... break
... print(i)
... 0
1
2
3
>>> 
```

Auto-indent won’t be applied if the previous two lines were all spaces. This means that you can finish entering a compound statement by pressing RETURN twice, and then a third press will finish and execute.

5.2.2 Auto-completion

While typing a command at the REPL, if the line typed so far corresponds to the beginning of the name of something, then pressing TAB will show possible things that could be entered. For example, first import the machine module by entering `import machine` and pressing RETURN. Then type `m` and press TAB and it should expand to `machine`. Enter a dot . and press TAB again. You should see something like:
The word will be expanded as much as possible until multiple possibilities exist. For example, type `machine.Pin.AF3` and press TAB and it will expand to `machine.Pin.AF3_TIM`. Pressing TAB a second time will show the possible expansions:

```python
>>> machine.Pin.AF3_TIM
AF3_TIM10  AF3_TIM11  AF3_TIM8  AF3_TIM9
>>> machine.Pin.AF3_TIM
```

### 5.2.3 Interrupting a running program

You can interrupt a running program by pressing Ctrl-C. This will raise a `KeyboardInterrupt` which will bring you back to the REPL, providing your program doesn’t intercept the `KeyboardInterrupt` exception.

For example:

```python
>>> for i in range(1000000):
...     print(i)
... 0 1 2 3 ...
6466 6467 6468
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
KeyboardInterrupt:
>>> 
```

### 5.2.4 Paste Mode

If you want to paste some code into your terminal window, the auto-indent feature will mess things up. For example, if you had the following python code:

```python
def foo():
    print('This is a test to show paste mode')
    print('Here is a second line')
foo()
```

and you try to paste this into the normal REPL, then you will see something like this:

```python
>>> def foo():
...     print('This is a test to show paste mode')
...     print('Here is a second line')
...     foo()
... 
```
If you press Ctrl-E, then you will enter paste mode, which essentially turns off the auto-indent feature, and changes the prompt from `>>>` to `===`. For example:

```python
>>> paste mode; Ctrl-C to cancel, Ctrl-D to finish
=== def foo():
===     print('This is a test to show paste mode')
===     print('Here is a second line')
=== foo()
===
This is a test to show paste mode
Here is a second line
```  

Paste Mode allows blank lines to be pasted. The pasted text is compiled as if it were a file. Pressing Ctrl-D exits paste mode and initiates the compilation.

### 5.2.5 Soft Reset

A soft reset will reset the python interpreter, but tries not to reset the method by which you’re connected to the MicroPython board (USB-serial, or Wifi).

You can perform a soft reset from the REPL by pressing Ctrl-D, or from your python code by executing:

```python
machine.soft_reset()
```

For example, if you reset your MicroPython board, and you execute a `dir()` command, you’d see something like this:

```python
>>> dir()
['__name__', 'pyb']
```

Now create some variables and repeat the `dir()` command:

```python
>>> i = 1
>>> j = 23
>>> x = 'abc'
>>> dir()
['j', 'x', '__name__', 'pyb', 'i']
```  

Now if you enter Ctrl-D, and repeat the `dir()` command, you’ll see that your variables no longer exist:

```
PYB: sync filesystems
PYB: soft reboot
MicroPython v1.5-51-g6f70283-dirty on 2015-10-30; PYBv1.0 with STM32F405RG
Type "help()" for more information.
>>> dir()
['__name__', 'pyb']
```
5.2.6 The special variable _ (underscore)

When you use the REPL, you may perform computations and see the results. MicroPython stores the results of the previous statement in the variable _ (underscore). So you can use the underscore to save the result in a variable. For example:

```
>>> 1 + 2 + 3 + 4 + 5
15
>>> x = _
>>> x
15
``` 

5.2.7 Raw Mode

Raw mode is not something that a person would normally use. It is intended for programmatic use. It essentially behaves like paste mode with echo turned off.

Raw mode is entered using Ctrl-A. You then send your python code, followed by a Ctrl-D. The Ctrl-D will be acknowledged by ‘OK’ and then the python code will be compiled and executed. Any output (or errors) will be sent back. Entering Ctrl-B will leave raw mode and return the the regular (aka friendly) REPL.

The tools/pyboard.py program uses the raw REPL to execute python files on the MicroPython board.

5.3 Writing interrupt handlers

On suitable hardware MicroPython offers the ability to write interrupt handlers in Python. Interrupt handlers - also known as interrupt service routines (ISR’s) - are defined as callback functions. These are executed in response to an event such as a timer trigger or a voltage change on a pin. Such events can occur at any point in the execution of the program code. This carries significant consequences, some specific to the MicroPython language. Others are common to all systems capable of responding to real time events. This document covers the language specific issues first, followed by a brief introduction to real time programming for those new to it.

This introduction uses vague terms like “slow” or “as fast as possible”. This is deliberate, as speeds are application dependent. Acceptable durations for an ISR are dependent on the rate at which interrupts occur, the nature of the main program, and the presence of other concurrent events.

5.3.1 Tips and recommended practices

This summarises the points detailed below and lists the principal recommendations for interrupt handler code.

- Keep the code as short and simple as possible.
- Avoid memory allocation: no appending to lists or insertion into dictionaries, no floating point.
- Consider using `micropython.schedule` to work around the above constraint.
- Where an ISR returns multiple bytes use a pre-allocated `bytearray`. If multiple integers are to be shared between an ISR and the main program consider an array (`array.array`).
- Where data is shared between the main program and an ISR, consider disabling interrupts prior to accessing the data in the main program and re-enabling them immediately afterwards (see Critical Sections).
- Allocate an emergency exception buffer (see below).
5.3.2 MicroPython Issues

The emergency exception buffer

If an error occurs in an ISR, MicroPython is unable to produce an error report unless a special buffer is created for the purpose. Debugging is simplified if the following code is included in any program using interrupts.

```python
import micropython
micropython.alloc_emergency_exception_buf(100)
```

Simplicity

For a variety of reasons it is important to keep ISR code as short and simple as possible. It should do only what has to be done immediately after the event which caused it: operations which can be deferred should be delegated to the main program loop. Typically an ISR will deal with the hardware device which caused the interrupt, making it ready for the next interrupt to occur. It will communicate with the main loop by updating shared data to indicate that the interrupt has occurred, and it will return. An ISR should return control to the main loop as quickly as possible. This is not a specific MicroPython issue so is covered in more detail below.

Communication between an ISR and the main program

Normally an ISR needs to communicate with the main program. The simplest means of doing this is via one or more shared data objects, either declared as global or shared via a class (see below). There are various restrictions and hazards around doing this, which are covered in more detail below. Integers, bytes and bytearray objects are commonly used for this purpose along with arrays (from the array module) which can store various data types.

The use of object methods as callbacks

MicroPython supports this powerful technique which enables an ISR to share instance variables with the underlying code. It also enables a class implementing a device driver to support multiple device instances. The following example causes two LED’s to flash at different rates.

```python
import pyb, micropython
micropython.alloc_emergency_exception_buf(100)

class Foo(object):
    def __init__(self, timer, led):
        self.led = led
        timer.callback(self.cb)
    def cb(self, tim):
        self.led.toggle()

red = Foo(pyb.Timer(4, freq=1), pyb.LED(1))
green = Foo(pyb.Timer(2, freq=0.8), pyb.LED(2))
```

In this example the red instance associates timer 4 with LED 1: when a timer 4 interrupt occurs red.cb() is called causing LED 1 to change state. The green instance operates similarly: a timer 2 interrupt results in the execution of green.cb() and toggles LED 2. The use of instance methods confers two benefits. Firstly a single class enables code to be shared between multiple hardware instances. Secondly, as a bound method the callback function’s first argument is self. This enables the callback to access instance data and to save state between successive calls. For example, if the class above had a variable self.count set to zero in the constructor, cb() could increment the counter. The red and green instances would then maintain independent counts of the number of times each LED had changed state.

5.3. Writing interrupt handlers
Creation of Python objects

ISR’s cannot create instances of Python objects. This is because MicroPython needs to allocate memory for the object from a store of free memory block called the heap. This is not permitted in an interrupt handler because heap allocation is not re-entrant. In other words the interrupt might occur when the main program is part way through performing an allocation - to maintain the integrity of the heap the interpreter disallows memory allocations in ISR code.

A consequence of this is that ISR’s can’t use floating point arithmetic; this is because floats are Python objects. Similarly an ISR can’t append an item to a list. In practice it can be hard to determine exactly which code constructs will attempt to perform memory allocation and provoke an error message: another reason for keeping ISR code short and simple.

One way to avoid this issue is for the ISR to use pre-allocated buffers. For example a class constructor creates a bytearray instance and a boolean flag. The ISR method assigns data to locations in the buffer and sets the flag. The memory allocation occurs in the main program code when the object is instantiated rather than in the ISR.

The MicroPython library I/O methods usually provide an option to use a pre-allocated buffer. For example pyb.i2c.recv() can accept a mutable buffer as its first argument: this enables its use in an ISR.

A means of creating an object without employing a class or globals is as follows:

```python
def set_volume(t, buf=bytearray(3)):
    buf[0] = 0xa5
    buf[1] = t >> 4
    buf[2] = 0x5a
    return buf
```

The compiler instantiates the default `buf` argument when the function is loaded for the first time (usually when the module it’s in is imported).

An instance of object creation occurs when a reference to a bound method is created. This means that an ISR cannot pass a bound method to a function. One solution is to create a reference to the bound method in the class constructor and to pass that reference in the ISR. For example:

```python
class Foo():
    def __init__(self):
        self.bar_ref = self.bar  # Allocation occurs here
        self.x = 0.1
        tim = pyb.Timer(4)
        tim.init(freq=2)
        tim.callback(self.cb)

    def bar(self, _):
        self.x *= 1.2
        print(self.x)

    def cb(self, t):
        # Passing self.bar would cause allocation.
        micropython.schedule(self.bar_ref, 0)
```

Other techniques are to define and instantiate the method in the constructor or to pass `Foo.bar()` with the argument `self`.

Use of Python objects

A further restriction on objects arises because of the way Python works. When an `import` statement is executed the Python code is compiled to bytecode, with one line of code typically mapping to multiple bytecodes. When the code runs the interpreter reads each bytecode and executes it as a series of machine code instructions. Given that
an interrupt can occur at any time between machine code instructions, the original line of Python code may be only partially executed. Consequently a Python object such as a set, list or dictionary modified in the main loop may lack internal consistency at the moment the interrupt occurs.

A typical outcome is as follows. On rare occasions the ISR will run at the precise moment in time when the object is partially updated. When the ISR tries to read the object, a crash results. Because such problems typically occur on rare, random occasions they can be hard to diagnose. There are ways to circumvent this issue, described in Critical Sections below.

It is important to be clear about what constitutes the modification of an object. An alteration to a built-in type such as a dictionary is problematic. Altering the contents of an array or bytearray is not. This is because bytes or words are written as a single machine code instruction which is not interruptible: in the parlance of real time programming the write is atomic. A user defined object might instantiate an integer, array or bytearray. It is valid for both the main loop and the ISR to alter the contents of these.

MicroPython supports integers of arbitrary precision. Values between $2^{30} - 1$ and $-2^{30}$ will be stored in a single machine word. Larger values are stored as Python objects. Consequently changes to long integers cannot be considered atomic. The use of long integers in ISR’s is unsafe because memory allocation may be attempted as the variable’s value changes.

**Overcoming the float limitation**

In general it is best to avoid using floats in ISR code: hardware devices normally handle integers and conversion to floats is normally done in the main loop. However there are a few DSP algorithms which require floating point. On platforms with hardware floating point (such as the Pyboard) the inline ARM Thumb assembler can be used to work round this limitation. This is because the processor stores float values in a machine word; values can be shared between the ISR and main program code via an array of floats.

**Using micropython.schedule**

This function enables an ISR to schedule a callback for execution “very soon”. The callback is queued for execution which will take place at a time when the heap is not locked. Hence it can create Python objects and use floats. The callback is also guaranteed to run at a time when the main program has completed any update of Python objects, so the callback will not encounter partially updated objects.

Typical usage is to handle sensor hardware. The ISR acquires data from the hardware and enables it to issue a further interrupt. It then schedules a callback to process the data.

Scheduled callbacks should comply with the principles of interrupt handler design outlined below. This is to avoid problems resulting from I/O activity and the modification of shared data which can arise in any code which pre-empts the main program loop.

Execution time needs to be considered in relation to the frequency with which interrupts can occur. If an interrupt occurs while the previous callback is executing, a further instance of the callback will be queued for execution; this will run after the current instance has completed. A sustained high interrupt repetition rate therefore carries a risk of unconstrained queue growth and eventual failure with a `RuntimeError`.

If the callback to be passed to `schedule()` is a bound method, consider the note in “Creation of Python objects”.

### 5.3.3 Exceptions

If an ISR raises an exception it will not propagate to the main loop. The interrupt will be disabled unless the exception is handled by the ISR code.
5.3.4 General Issues

This is merely a brief introduction to the subject of real time programming. Beginners should note that design errors in real time programs can lead to faults which are particularly hard to diagnose. This is because they can occur rarely and at intervals which are essentially random. It is crucial to get the initial design right and to anticipate issues before they arise. Both interrupt handlers and the main program need to be designed with an appreciation of the following issues.

Interrupt Handler Design

As mentioned above, ISR’s should be designed to be as simple as possible. They should always return in a short, predictable period of time. This is important because when the ISR is running, the main loop is not: inevitably the main loop experiences pauses in its execution at random points in the code. Such pauses can be a source of hard to diagnose bugs particularly if their duration is long or variable. In order to understand the implications of ISR run time, a basic grasp of interrupt priorities is required.

Interrupts are organised according to a priority scheme. ISR code may itself be interrupted by a higher priority interrupt. This has implications if the two interrupts share data (see Critical Sections below). If such an interrupt occurs it interposes a delay into the ISR code. If a lower priority interrupt occurs while the ISR is running, it will be delayed until the ISR is complete: if the delay is too long, the lower priority interrupt may fail. A further issue with slow ISR’s is the case where a second interrupt of the same type occurs during its execution. The second interrupt will be handled on termination of the first. However if the rate of incoming interrupts consistently exceeds the capacity of the ISR to service them the outcome will not be a happy one.

Consequently looping constructs should be avoided or minimised. I/O to devices other than to the interrupting device should normally be avoided: I/O such as disk access, print statements and UART access is relatively slow, and its duration may vary. A further issue here is that filesystem functions are not reentrant: using filesystem I/O in an ISR and the main program would be hazardous. Crucially ISR code should not wait on an event. I/O is acceptable if the code can be guaranteed to return in a predictable period, for example toggling a pin or LED. Accessing the interrupting device via I2C or SPI may be necessary but the time taken for such accesses should be calculated or measured and its impact on the application assessed.

There is usually a need to share data between the ISR and the main loop. This may be done either through global variables or via class or instance variables. Variables are typically integer or boolean types, or integer or byte arrays (a pre-allocated integer array offers faster access than a list). Where multiple values are modified by the ISR it is necessary to consider the case where the interrupt occurs at a time when the main program has accessed some, but not all, of the values. This can lead to inconsistencies.

Consider the following design. An ISR stores incoming data in a bytearray, then adds the number of bytes received to an integer representing total bytes ready for processing. The main program reads the number of bytes, processes the bytes, then clears down the number of bytes ready. This will work until an interrupt occurs just after the main program has read the number of bytes. The ISR puts the added data into the buffer and updates the number received, but the main program has already read the number, so processes the data originally received. The newly arrived bytes are lost.

There are various ways of avoiding this hazard, the simplest being to use a circular buffer. If it is not possible to use a structure with inherent thread safety other ways are described below.

Reentrancy

A potential hazard may occur if a function or method is shared between the main program and one or more ISR’s or between multiple ISR’s. The issue here is that the function may itself be interrupted and a further instance of that function run. If this is to occur, the function must be designed to be reentrant. How this is done is an advanced topic beyond the scope of this tutorial.
Critical Sections

An example of a critical section of code is one which accesses more than one variable which can be affected by an ISR. If the interrupt happens to occur between accesses to the individual variables, their values will be inconsistent. This is an instance of a hazard known as a race condition: the ISR and the main program loop race to alter the variables. To avoid inconsistency a means must be employed to ensure that the ISR does not alter the values for the duration of the critical section. One way to achieve this is to issue `pyb.disable_irq()` before the start of the section, and `pyb.enable_irq()` at the end. Here is an example of this approach:

```python
import pyb, micropython, array
micropython.alloc_emergency_exception_buf(100)

class BoundsException(Exception):
    pass

ARRAYSIZE = const(20)
index = 0
data = array.array('i', 0 for x in range(ARRAYSIZE))

def callback1(t):
    global data, index
    for x in range(5):
        data[index] = pyb.rng()  # simulate input
        index += 1
        if index >= ARRAYSIZE:
            raise BoundsException('Array bounds exceeded')

tim4 = pyb.Timer(4, freq=100, callback=callback1)

for loop in range(1000):
    if index > 0:
        irq_state = pyb.disable_irq()  # Start of critical section
        for x in range(index):
            print(data[x])
        index = 0
        pyb.enable_irq(irq_state)  # End of critical section
        print('loop {}/{}'.format(loop))
pyb.delay(1)
tim4.callback(None)
```

A critical section can comprise a single line of code and a single variable. Consider the following code fragment.

```python
count = 0
def cb():  # An interrupt callback
    count += 1

def main():
    # Code to set up the interrupt callback omitted
    while True:
        count += 1
```

This example illustrates a subtle source of bugs. The line `count += 1` in the main loop carries a specific race condition hazard known as a read-modify-write. This is a classic cause of bugs in real time systems. In the main loop MicroPython reads the value of `t.counter` adds 1 to it, and writes it back. On rare occasions the interrupt occurs after the read and before the write. The interrupt modifies `t.counter` but its change is overwritten by the main loop when the ISR returns. In a real system this could lead to rare, unpredictable failures.

As mentioned above, care should be taken if an instance of a Python built in type is modified in the main code and that

5.3. Writing interrupt handlers
instance is accessed in an ISR. The code performing the modification should be regarded as a critical section to ensure that the instance is in a valid state when the ISR runs.

Particular care needs to be taken if a dataset is shared between different ISR’s. The hazard here is that the higher priority interrupt may occur when the lower priority one has partially updated the shared data. Dealing with this situation is an advanced topic beyond the scope of this introduction other than to note that mutex objects described below can sometimes be used.

Disabling interrupts for the duration of a critical section is the usual and simplest way to proceed, but it disables all interrupts rather than merely the one with the potential to cause problems. It is generally undesirable to disable an interrupt for long. In the case of timer interrupts it introduces variability to the time when a callback occurs. In the case of device interrupts, it can lead to the device being serviced too late with possible loss of data or overrun errors in the device hardware. Like ISR’s, a critical section in the main code should have a short, predictable duration.

An approach to dealing with critical sections which radically reduces the time for which interrupts are disabled is to use an object termed a mutex (name derived from the notion of mutual exclusion). The main program locks the mutex before running the critical section and unlocks it at the end. The ISR tests whether the mutex is locked. If it is, it avoids the critical section and returns. The design challenge is defining what the ISR should do in the event that access to the critical variables is denied. A simple example of a mutex may be found here. Note that the mutex code does disable interrupts, but only for the duration of eight machine instructions: the benefit of this approach is that other interrupts are virtually unaffected.

Interrupts and the REPL

Interrupt handlers, such as those associated with timers, can continue to run after a program terminates. This may produce unexpected results where you might have expected the object raising the callback to have gone out of scope. For example on the Pyboard:

```python
def bar():
    foo = pyb.Timer(2, freq=4, callback=lambda t: print('.', end=''))
bar()
```

This continues to run until the timer is explicitly disabled or the board is reset with `ctrl D`.

  - MicroPython code improvements

Chapter 5. The MicroPython language
This tutorial describes ways of improving the performance of MicroPython code. Optimisations involving other languages are covered elsewhere, namely the use of modules written in C and the MicroPython inline assembler.

The process of developing high performance code comprises the following stages which should be performed in the order listed.

• Design for speed.
• Code and debug.

Optimisation steps:

• Identify the slowest section of code.
• Improve the efficiency of the Python code.
• Use the native code emitter.
• Use the viper code emitter.
• Use hardware-specific optimisations.

5.4.1 Designing for speed

Performance issues should be considered at the outset. This involves taking a view on the sections of code which are most performance critical and devoting particular attention to their design. The process of optimisation begins when the code has been tested: if the design is correct at the outset optimisation will be straightforward and may actually be unnecessary.

Algorithms

The most important aspect of designing any routine for performance is ensuring that the best algorithm is employed. This is a topic for textbooks rather than for a MicroPython guide but spectacular performance gains can sometimes be achieved by adopting algorithms known for their efficiency.

RAM Allocation

To design efficient MicroPython code it is necessary to have an understanding of the way the interpreter allocates RAM. When an object is created or grows in size (for example where an item is appended to a list) the necessary RAM is allocated from a block known as the heap. This takes a significant amount of time; further it will on occasion trigger a process known as garbage collection which can take several milliseconds.

Consequently the performance of a function or method can be improved if an object is created once only and not permitted to grow in size. This implies that the object persists for the duration of its use: typically it will be instantiated in a class constructor and used in various methods.

This is covered in further detail Controlling garbage collection below.
Buffers

An example of the above is the common case where a buffer is required, such as one used for communication with a device. A typical driver will create the buffer in the constructor and use it in its I/O methods which will be called repeatedly.

The MicroPython libraries typically provide support for pre-allocated buffers. For example, objects which support stream interface (e.g., file or UART) provide `read()` method which allocates new buffer for read data, but also a `readinto()` method to read data into an existing buffer.

Floating Point

Some MicroPython ports allocate floating point numbers on heap. Some other ports may lack dedicated floating-point coprocessor, and perform arithmetic operations on them in “software” at considerably lower speed than on integers. Where performance is important, use integer operations and restrict the use of floating point to sections of the code where performance is not paramount. For example, capture ADC readings as integers values to an array in one quick go, and only then convert them to floating-point numbers for signal processing.

Arrays

Consider the use of the various types of array classes as an alternative to lists. The `array` module supports various element types with 8-bit elements supported by Python’s built in `bytes` and `bytearray` classes. These data structures all store elements in contiguous memory locations. Once again to avoid memory allocation in critical code these should be pre-allocated and passed as arguments or as bound objects.

When passing slices of objects such as `bytearray` instances, Python creates a copy which involves allocation of the size proportional to the size of slice. This can be alleviated using a `memoryview` object. `memoryview` itself is allocated on heap, but is a small, fixed-size object, regardless of the size of slice it points too.

```
ba = bytearray(10000)  # big array
func(ba[30:2000])     # a copy is passed, ~2K new allocation
mv = memoryview(ba)   # small object is allocated
func(mv[30:2000])     # a pointer to memory is passed
```

A `memoryview` can only be applied to objects supporting the buffer protocol - this includes arrays but not lists. Small caveat is that while memoryview object is live, it also keeps alive the original buffer object. So, a memoryview isn’t a universal panacea. For instance, in the example above, if you are done with 10K buffer and just need those bytes 30:2000 from it, it may be better to make a slice, and let the 10K buffer go (be ready for garbage collection), instead of making a long-living memoryview and keeping 10K blocked for GC.

Nonetheless, `memoryview` is indispensable for advanced preallocated buffer management. `readinto()` method discussed above puts data at the beginning of buffer and fills in entire buffer. What if you need to put data in the middle of existing buffer? Just create a memoryview into the needed section of buffer and pass it to `readinto()`.

5.4.2 Identifying the slowest section of code

This is a process known as profiling and is covered in textbooks and (for standard Python) supported by various software tools. For the type of smaller embedded application likely to be running on MicroPython platforms the slowest function or method can usually be established by judicious use of the timing `ticks` group of functions documented in `utime`. Code execution time can be measured in ms, us, or CPU cycles.

The following enables any function or method to be timed by adding an `@timed_function` decorator:
```python
def timed_function(f, *args, **kwargs):
    myname = str(f).split(' ')[1]
    def new_func(*args, **kwargs):
        t = utime.ticks_us()
        result = f(*args, **kwargs)
        delta = utime.ticks_diff(utime.ticks_us(), t)
        print('Function {} Time = {:6.3f}ms'.format(myname, delta/1000))
        return result
    return new_func
```

5.4.3 MicroPython code improvements

The `const()` declaration

MicroPython provides a `const()` declaration. This works in a similar way to `#define` in C in that when the code is compiled to bytecode the compiler substitutes the numeric value for the identifier. This avoids a dictionary lookup at runtime. The argument to `const()` may be anything which, at compile time, evaluates to an integer e.g. `0x100` or `1 << 8`.

Caching object references

Where a function or method repeatedly accesses objects performance is improved by caching the object in a local variable:

```python
class foo(object):
    def __init__(self):
        ba = bytearray(100)
    def bar(self, obj_display):
        ba_ref = self.ba
        fb = obj_display.framebuffer
        # iterative code using these two objects
```

This avoids the need repeatedly to look up `self.ba` and `obj_display.framebuffer` in the body of the method `bar()`.

Controlling garbage collection

When memory allocation is required, MicroPython attempts to locate an adequately sized block on the heap. This may fail, usually because the heap is cluttered with objects which are no longer referenced by code. If a failure occurs, the process known as garbage collection reclaims the memory used by these redundant objects and the allocation is then tried again - a process which can take several milliseconds.

There may be benefits in pre-empting this by periodically issuing `gc.collect()`. Firstly doing a collection before it is actually required is quicker - typically on the order of 1ms if done frequently. Secondly you can determine the point in code where this time is used rather than have a longer delay occur at random points, possibly in a speed critical section. Finally performing collections regularly can reduce fragmentation in the heap. Severe fragmentation can lead to non-recoverable allocation failures.

5.4.4 The Native code emitter

This causes the MicroPython compiler to emit native CPU opcodes rather than bytecode. It covers the bulk of the MicroPython functionality, so most functions will require no adaptation (but see below). It is invoked by means of a
There are certain limitations in the current implementation of the native code emitter.

- Context managers are not supported (the `with` statement).
- Generators are not supported.
- If `raise` is used an argument must be supplied.

The trade-off for the improved performance (roughly twice as fast as bytecode) is an increase in compiled code size.

### 5.4.5 The Viper code emitter

The optimisations discussed above involve standards-compliant Python code. The Viper code emitter is not fully compliant. It supports special Viper native data types in pursuit of performance. Integer processing is non-compliant because it uses machine words: arithmetic on 32 bit hardware is performed modulo $2^{32}$.

Like the Native emitter Viper produces machine instructions but further optimisations are performed, substantially increasing performance especially for integer arithmetic and bit manipulations. It is invoked using a decorator:

```python
@micropython.viper
def foo(self, arg: int) -> int:
    # code
```

As the above fragment illustrates it is beneficial to use Python type hints to assist the Viper optimiser. Type hints provide information on the data types of arguments and of the return value; these are a standard Python language feature formally defined here PEP0484. Viper supports its own set of types namely `int`, `uint` (unsigned integer), `ptr`, `ptr8`, `ptr16` and `ptr32`. The `ptrX` types are discussed below. Currently the `uint` type serves a single purpose: as a type hint for a function return value. If such a function returns `0xffffffff` Python will interpret the result as $2^{32} -1$ rather than as `-1`.

In addition to the restrictions imposed by the native emitter the following constraints apply:

- Functions may have up to four arguments.
- Default argument values are not permitted.
- Floating point may be used but is not optimised.

Viper provides pointer types to assist the optimiser. These comprise

- `ptr` Pointer to an object.
- `ptr8` Points to a byte.
- `ptr16` Points to a 16 bit half-word.
- `ptr32` Points to a 32 bit machine word.

The concept of a pointer may be unfamiliar to Python programmers. It has similarities to a Python `memoryview` object in that it provides direct access to data stored in memory. Items are accessed using subscript notation, but slices are not supported: a pointer can return a single item only. Its purpose is to provide fast random access to data stored in contiguous memory locations - such as data stored in objects which support the buffer protocol, and memory-mapped peripheral registers in a microcontroller. It should be noted that programming using pointers is hazardous: bounds checking is not performed and the compiler does nothing to prevent buffer overrun errors.
Typical usage is to cache variables:

```python
@micropython.viper
def foo(self, arg: int) -> int:
    buf = ptr8(self.linebuf)  # self.linebuf is a bytearray or bytes object
    for x in range(20, 30):
        bar = buf[x]  # Access a data item through the pointer
        # code omitted
```

In this instance the compiler “knows” that `buf` is the address of an array of bytes; it can emit code to rapidly compute the address of `buf[x]` at runtime. Where casts are used to convert objects to Viper native types these should be performed at the start of the function rather than in critical timing loops as the cast operation can take several microseconds. The rules for casting are as follows:

- Casting operators are currently: `int`, `bool`, `uint`, `ptr`, `ptr8`, `ptr16` and `ptr32`.
- The result of a cast will be a native Viper variable.
- Arguments to a cast can be a Python object or a native Viper variable.
- If argument is a native Viper variable, then cast is a no-op (i.e. costs nothing at runtime) that just changes the type (e.g. from `uint` to `ptr8`) so that you can then store/load using this pointer.
- If the argument is a Python object and the cast is `int` or `uint`, then the Python object must be of integral type and the value of that integral object is returned.
- The argument to a bool cast must be integral type (boolean or integer); when used as a return type the viper function will return True or False objects.
- If the argument is a Python object and the cast is `ptr`, `ptr`, `ptr16` or `ptr32`, then the Python object must either have the buffer protocol with read-write capabilities (in which case a pointer to the start of the buffer is returned) or it must be of integral type (in which case the value of that integral object is returned).

The following example illustrates the use of a `ptr16` cast to toggle pin X1 n times:

```python
BIT0 = const(1)
@micropython.viper
def toggle_n(n: int):
    odr = ptr16(stm.GPIOA + stm.GPIO_ODR)
    for _ in range(n):
        odr[0] ^= BIT0
```

A detailed technical description of the three code emitters may be found on Kickstarter here Note 1 and here Note 2

5.4.6 Accessing hardware directly

**Note:** Code examples in this section are given for the Pyboard. The techniques described however may be applied to other MicroPython ports too.

This comes into the category of more advanced programming and involves some knowledge of the target MCU. Consider the example of toggling an output pin on the Pyboard. The standard approach would be to write

```python
mipin.value(mipin.value() ^ 1)  # mipin was instantiated as an output pin
```

This involves the overhead of two calls to the `Pin` instance’s `value()` method. This overhead can be eliminated by performing a read/write to the relevant bit of the chip’s GPIO port output data register (odr). To facilitate this the `stm`
module provides a set of constants providing the addresses of the relevant registers. A fast toggle of pin P4 (CPU pin A14) - corresponding to the green LED - can be performed as follows:

```python
import machine
import stm
BIT14 = const(1 << 14)
machine.mem16[stm.GPIOA + stm.GPIO_ODR] ^= BIT14
```

### 5.5 MicroPython on Microcontrollers

MicroPython is designed to be capable of running on microcontrollers. These have hardware limitations which may be unfamiliar to programmers more familiar with conventional computers. In particular the amount of RAM and non-volatile “disk” (flash memory) storage is limited. This tutorial offers ways to make the most of the limited resources. Because MicroPython runs on controllers based on a variety of architectures, the methods presented are generic: in some cases it will be necessary to obtain detailed information from platform specific documentation.

#### 5.5.1 Flash Memory

On the Pyboard the simple way to address the limited capacity is to fit a micro SD card. In some cases this is impractical, either because the device does not have an SD card slot or for reasons of cost or power consumption; hence the on-chip flash must be used. The firmware including the MicroPython subsystem is stored in the onboard flash. The remaining capacity is available for use. For reasons connected with the physical architecture of the flash memory part of this capacity may be inaccessible as a filesystem. In such cases this space may be employed by incorporating user modules into a firmware build which is then flashed to the device.

There are two ways to achieve this: frozen modules and frozen bytecode. Frozen modules store the Python source with the firmware. Frozen bytecode uses the cross compiler to convert the source to bytecode which is then stored with the firmware. In either case the module may be accessed with an import statement:

```python
import mymodule
```

The procedure for producing frozen modules and bytecode is platform dependent; instructions for building the firmware can be found in the README files in the relevant part of the source tree.

In general terms the steps are as follows:

- Clone the MicroPython repository.
- Acquire the (platform specific) toolchain to build the firmware.
- Build the cross compiler.
- Place the modules to be frozen in a specified directory (dependent on whether the module is to be frozen as source or as bytecode).
- Build the firmware. A specific command may be required to build frozen code of either type - see the platform documentation.
- Flash the firmware to the device.

#### 5.5.2 RAM

When reducing RAM usage there are two phases to consider: compilation and execution. In addition to memory consumption, there is also an issue known as heap fragmentation. In general terms it is best to minimise the repeated
creation and destruction of objects. The reason for this is covered in the section covering the heap.

## Compilation Phase

When a module is imported, MicroPython compiles the code to bytecode which is then executed by the MicroPython virtual machine (VM). The bytecode is stored in RAM. The compiler itself requires RAM, but this becomes available for use when the compilation has completed.

If a number of modules have already been imported the situation can arise where there is insufficient RAM to run the compiler. In this case the import statement will produce a memory exception.

If a module instantiates global objects on import it will consume RAM at the time of import, which is then unavailable for the compiler to use on subsequent imports. In general it is best to avoid code which runs on import; a better approach is to have initialisation code which is run by the application after all modules have been imported. This maximises the RAM available to the compiler.

If RAM is still insufficient to compile all modules one solution is to precompile modules. MicroPython has a cross compiler capable of compiling Python modules to bytecode (see the README in the mpy-cross directory). The resulting bytecode file has a .mpy extension; it may be copied to the filesystem and imported in the usual way. Alternatively some or all modules may be implemented as frozen bytecode: on most platforms this saves even more RAM as the bytecode is run directly from flash rather than being stored in RAM.

## Execution Phase

There are a number of coding techniques for reducing RAM usage.

### Constants

MicroPython provides a `const` keyword which may be used as follows:

```python
from micropython import const
ROWS = const(33)
_COLS = const(0x10)
a = ROWS
b = _COLS
```

In both instances where the constant is assigned to a variable the compiler will avoid coding a lookup to the name of the constant by substituting its literal value. This saves bytecode and hence RAM. However the `ROWS` value will occupy at least two machine words, one each for the key and value in the globals dictionary. The presence in the dictionary is necessary because another module might import or use it. This RAM can be saved by prepending the name with an underscore as in `_COLS`: this symbol is not visible outside the module so will not occupy RAM.

The argument to `const()` may be anything which, at compile time, evaluates to an integer e.g. `0x100` or `1 << 8`. It can even include other `const` symbols that have already been defined, e.g. `1 << BIT`.

### Constant data structures

Where there is a substantial volume of constant data and the platform supports execution from Flash, RAM may be saved as follows. The data should be located in Python modules and frozen as bytecode. The data must be defined as `bytes` objects. The compiler ‘knows’ that `bytes` objects are immutable and ensures that the objects remain in flash memory rather than being copied to RAM. The `ustruct` module can assist in converting between `bytes` types and other Python built-in types.

When considering the implications of frozen bytecode, note that in Python strings, floats, bytes, integers and complex numbers are immutable. Accordingly these will be frozen into flash. Thus, in the line

```python
mysting = "The quick brown fox"
```
the actual string “The quick brown fox” will reside in flash. At runtime a reference to the string is assigned to the `variable` `mystring`. The reference occupies a single machine word. In principle a long integer could be used to store constant data:

```python
bar = 0xDEADBEEF0000DEADBEEF
```

As in the string example, at runtime a reference to the arbitrarily large integer is assigned to the variable `bar`. That reference occupies a single machine word.

It might be expected that tuples of integers could be employed for the purpose of storing constant data with minimal RAM use. With the current compiler this is ineffective (the code works, but RAM is not saved).

```python
foo = (1, 2, 3, 4, 5, 6, 100000)
```

At runtime the tuple will be located in RAM. This may be subject to future improvement.

**Needless object creation**

There are a number of situations where objects may unwittingly be created and destroyed. This can reduce the usability of RAM through fragmentation. The following sections discuss instances of this.

**String concatenation**

Consider the following code fragments which aim to produce constant strings:

```python
var = "foo" + "bar"
var1 = "foo" "bar"
var2 = "\nfoo\nbar"
```

Each produces the same outcome, however the first needlessly creates two string objects at runtime, allocates more RAM for concatenation before producing the third. The others perform the concatenation at compile time which is more efficient, reducing fragmentation.

Where strings must be dynamically created before being fed to a stream such as a file it will save RAM if this is done in a piecemeal fashion. Rather than creating a large string object, create a substring and feed it to the stream before dealing with the next.

The best way to create dynamic strings is by means of the string `format()` method:

```python
var = "Temperature {:5.2f} Pressure {:06d}\n".format(temp, press)
```

**Buffers**

When accessing devices such as instances of UART, I2C and SPI interfaces, using pre-allocated buffers avoids the creation of needless objects. Consider these two loops:

```python
while True:
    var = spi.read(100)
    # process data

buf = bytearray(100)
while True:
    spi.readinto(buf)
    # process data in buf
```

The first creates a buffer on each pass whereas the second re-uses a pre-allocated buffer; this is both faster and more efficient in terms of memory fragmentation.

**Bytes are smaller than ints**
On most platforms an integer consumes four bytes. Consider the two calls to the function `foo()`:

```python
def foo(bar):
    for x in bar:
        print(x)
foo((1, 2, 0xff))
foo(b'\1\2\xff')
```

In the first call a tuple of integers is created in RAM. The second efficiently creates a `bytes` object consuming the minimum amount of RAM. If the module were frozen as bytecode, the `bytes` object would reside in flash.

**Strings Versus Bytes**

Python3 introduced Unicode support. This introduced a distinction between a string and an array of bytes. MicroPython ensures that Unicode strings take no additional space so long as all characters in the string are ASCII (i.e. have a value < 126). If values in the full 8-bit range are required `bytes` and `bytearray` objects can be used to ensure that no additional space will be required. Note that most string methods (e.g. `str.strip()`) apply also to `bytes` instances so the process of eliminating Unicode can be painless.

```python
s = 'the quick brown fox'   # A string instance
b = b'the quick brown fox'  # A bytes instance
```

Where it is necessary to convert between strings and bytes the `str.encode()` and the `bytes.decode()` methods can be used. Note that both strings and bytes are immutable. Any operation which takes as input such an object and produces another implies at least one RAM allocation to produce the result. In the second line below a new bytes object is allocated. This would also occur if `foo` were a string.

```python
foo = b' empty whitespace'
foo = foo.lstrip()
```

**Runtime compiler execution**

The Python functions `eval` and `exec` invoke the compiler at runtime, which requires significant amounts of RAM. Note that the `pickle` library from `micropython-lib` employs `exec`. It may be more RAM efficient to use the `ujson` library for object serialisation.

**Storing strings in flash**

Python strings are immutable hence have the potential to be stored in read only memory. The compiler can place in flash strings defined in Python code. As with frozen modules it is necessary to have a copy of the source tree on the PC and the toolchain to build the firmware. The procedure will work even if the modules have not been fully debugged, so long as they can be imported and run.

After importing the modules, execute:

```python
micropython.qstr_info(1)
```

Then copy and paste all the Q(xxx) lines into a text editor. Check for and remove lines which are obviously invalid. Open the file qstrdefsport.h which will be found in ports/stm32 (or the equivalent directory for the architecture in use). Copy and paste the corrected lines at the end of the file. Save the file, rebuild and flash the firmware. The outcome can be checked by importing the modules and again issuing:

```python
micropython.qstr_info(1)
```

The Q(xxx) lines should be gone.
5.5.3 The Heap

When a running program instantiates an object the necessary RAM is allocated from a fixed size pool known as the heap. When the object goes out of scope (in other words becomes inaccessible to code) the redundant object is known as “garbage”. A process known as “garbage collection” (GC) reclaims that memory, returning it to the free heap. This process runs automatically, however it can be invoked directly by issuing `gc.collect()`.

The discourse on this is somewhat involved. For a ’quick fix’ issue the following periodically:

```python
gc.collect()
gc.threshold(gc.mem_free() // 4 + gc.mem_alloc())
```

**Fragmentation**

Say a program creates an object `foo`, then an object `bar`. Subsequently `foo` goes out of scope but `bar` remains. The RAM used by `foo` will be reclaimed by GC. However if `bar` was allocated to a higher address, the RAM reclaimed from `foo` will only be of use for objects no bigger than `foo`. In a complex or long running program the heap can become fragmented: despite there being a substantial amount of RAM available, there is insufficient contiguous space to allocate a particular object, and the program fails with a memory error.

The techniques outlined above aim to minimise this. Where large permanent buffers or other objects are required it is best to instantiate these early in the process of program execution before fragmentation can occur. Further improvements may be made by monitoring the state of the heap and by controlling GC; these are outlined below.

**Reporting**

A number of library functions are available to report on memory allocation and to control GC. These are to be found in the `gc` and `micropython` modules. The following example may be pasted at the REPL (`ctrl e` to enter paste mode, `ctrl d` to run it).

```python
import gc
import micropython

gc.collect()
micropython.mem_info()
print('-------------------------------')
print('Initial free: {} allocated: {}'.format(gc.mem_free(), gc.mem_alloc()))
def func():
    a = bytearray(10000)
gc.collect()
print('Func definition: {} allocated: {}'.format(gc.mem_free(), gc.mem_alloc()))
func()
print('Func run free: {} allocated: {}'.format(gc.mem_free(), gc.mem_alloc()))
gc.collect()
print('Garbage collect free: {} allocated: {}'.format(gc.mem_free(), gc.mem_alloc()))
print('-------------------------------')
micropython.mem_info(1)
```

Methods employed above:

- `gc.collect()` Force a garbage collection. See footnote.
- `micropython.mem_info()` Print a summary of RAM utilisation.
- `gc.mem_free()` Return the free heap size in bytes.
- `gc.mem_alloc()` Return the number of bytes currently allocated.
• `micropython.mem_info(1)` Print a table of heap utilisation (detailed below).

The numbers produced are dependent on the platform, but it can be seen that declaring the function uses a small amount of RAM in the form of bytecode emitted by the compiler (the RAM used by the compiler has been reclaimed). Running the function uses over 10KiB, but on return it is garbage because it is out of scope and cannot be referenced. The final `gc.collect()` recovers that memory.

The final output produced by `micropython.mem_info(1)` will vary in detail but may be interpreted as follows:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>free block</td>
</tr>
<tr>
<td>h</td>
<td>head block</td>
</tr>
<tr>
<td>=</td>
<td>tail block</td>
</tr>
<tr>
<td>m</td>
<td>marked head block</td>
</tr>
<tr>
<td>T</td>
<td>tuple</td>
</tr>
<tr>
<td>L</td>
<td>list</td>
</tr>
<tr>
<td>D</td>
<td>dict</td>
</tr>
<tr>
<td>F</td>
<td>float</td>
</tr>
<tr>
<td>B</td>
<td>byte code</td>
</tr>
<tr>
<td>M</td>
<td>module</td>
</tr>
</tbody>
</table>

Each letter represents a single block of memory, a block being 16 bytes. So each line of the heap dump represents 0x400 bytes or 1KiB of RAM.

**Control of Garbage Collection**

A GC can be demanded at any time by issuing `gc.collect()`. It is advantageous to do this at intervals, firstly to pre-empt fragmentation and secondly for performance. A GC can take several milliseconds but is quicker when there is little work to do (about 1ms on the Pyboard). An explicit call can minimise that delay while ensuring it occurs at points in the program when it is acceptable.

Automatic GC is provoked under the following circumstances. When an attempt at allocation fails, a GC is performed and the allocation re-tried. Only if this fails is an exception raised. Secondly an automatic GC will be triggered if the amount of free RAM falls below a threshold. This threshold can be adapted as execution progresses:

```python
gc.collect()
gc.threshold(gc.mem_free() // 4 + gc.mem_alloc())
```

This will provoke a GC when more than 25% of the currently free heap becomes occupied.

In general modules should instantiate data objects at runtime using constructors or other initialisation functions. The reason is that if this occurs on initialisation the compiler may be starved of RAM when subsequent modules are imported. If modules do instantiate data on import then `gc.collect()` issued after the import will ameliorate the problem.

**5.5.4 String Operations**

MicroPython handles strings in an efficient manner and understanding this can help in designing applications to run on microcontrollers. When a module is compiled, strings which occur multiple times are stored once only, a process known as string interning. In MicroPython an interned string is known as a qstr. In a module imported normally that single instance will be located in RAM, but as described above, in modules frozen as bytecode it will be located in flash.

5.5. MicroPython on Microcontrollers
String comparisons are also performed efficiently using hashing rather than character by character. The penalty for using strings rather than integers may hence be small both in terms of performance and RAM usage - a fact which may come as a surprise to C programmers.

5.5.5 Postscript

MicroPython passes, returns and (by default) copies objects by reference. A reference occupies a single machine word so these processes are efficient in RAM usage and speed.

Where variables are required whose size is neither a byte nor a machine word there are standard libraries which can assist in storing these efficiently and in performing conversions. See the array, ustruct and uctypes modules.

Footnote: gc.collect() return value

On Unix and Windows platforms the gc.collect() method returns an integer which signifies the number of distinct memory regions that were reclaimed in the collection (more precisely, the number of heads that were turned into frees). For efficiency reasons bare metal ports do not return this value.

5.6 Distribution packages, package management, and deploying applications

Just as the “big” Python, MicroPython supports creation of “third party” packages, distributing them, and easily installing them in each user’s environment. This chapter discusses how these actions are achieved. Some familiarity with Python packaging is recommended.

5.6.1 Overview

Steps below represent a high-level workflow when creating and consuming packages:

1. Python modules and packages are turned into distribution package archives, and published at the Python Package Index (PyPI).
2. upip package manager can be used to install a distribution package on a MicroPython port with networking capabilities (for example, on the Unix port).
3. For ports without networking capabilities, an “installation image” can be prepared on the Unix port, and transferred to a device by suitable means.
4. For low-memory ports, the installation image can be frozen as the bytecode into MicroPython executable, thus minimizing the memory storage overheads.

The sections below describe this process in details.

5.6.2 Distribution packages

Python modules and packages can be packaged into archives suitable for transfer between systems, storing at the well-known location (PyPI), and downloading on demand for deployment. These archives are known as distribution packages (to differentiate them from Python packages (means to organize Python source code)).

The MicroPython distribution package format is a well-known tar.gz format, with some adaptations however. The Gzip compressor, used as an external wrapper for TAR archives, by default uses 32KB dictionary size, which means that to uncompress a compressed stream, 32KB of contiguous memory needs to be allocated. This requirement may be
not satisfiable on low-memory devices, which may have total memory available less than that amount, and even if not, a contiguous block like that may be hard to allocate due to memory fragmentation. To accommodate these constraints, MicroPython distribution packages use Gzip compression with the dictionary size of 4K, which should be a suitable compromise with still achieving some compression while being able to uncompressed even by the smallest devices.

Besides the small compression dictionary size, MicroPython distribution packages also have other optimizations, like removing any files from the archive which aren’t used by the installation process. In particular, upip package manager doesn’t execute setup.py during installation (see below), and thus that file is not included in the archive.

At the same time, these optimizations make MicroPython distribution packages not compatible with CPython’s package manager, pip. This isn’t considered a big problem, because:

1. Packages can be installed with upip, and then can be used with CPython (if they are compatible with it).
2. In the other direction, majority of CPython packages would be incompatible with MicroPython by various reasons, first of all, the reliance on features not implemented by MicroPython.

Summing up, the MicroPython distribution package archives are highly optimized for MicroPython’s target environments, which are highly resource constrained devices.

### 5.6.3 upip package manager

MicroPython distribution packages are intended to be installed using the upip package manager. upip is a Python application which is usually distributed (as frozen bytecode) with network-enabled MicroPython ports. At the very least, upip is available in the MicroPython Unix port.

On any MicroPython port providing upip, it can be accessed as following:

```python
import upip
upip.help()
upip.install(package_or_package_list, [path])
```

Where package_or_package_list is the name of a distribution package to install, or a list of such names to install multiple packages. Optional path parameter specifies filesystem location to install under and defaults to the standard library location (see below).

An example of installing a specific package and then using it:

```python
>>> import upip
>>> upip.install("micropython-pystone_lowmem")
[...]
>>> import pystone_lowmem
>>> pystone_lowmem.main()
```

Note that the name of Python package and the name of distribution package for it in general don’t have to match, and oftentimes they don’t. This is because PyPI provides a central package repository for all different Python implementations and versions, and thus distribution package names may need to be namespaced for a particular implementation. For example, all packages from micropython-lib follow this naming convention: for a Python module or package named foo, the distribution package name is micropython-foo.

For the ports which run MicroPython executable from the OS command prompts (like the Unix port), upip can be (and indeed, usually is) run from the command line instead of MicroPython’s own REPL. The commands which corresponds to the example above are:

```
micropython -m upip -h
micropython -m upip install [-p <path>] <packages>...
micropython -m upip install micropython-pystone_lowmem
```

[TODO: Describe installation path.]
5.6.4 Cross-installing packages

For MicroPython ports without native networking capabilities, the recommend process is “cross-installing” them into a “directory image” using the MicroPython Unix port, and then transferring this image to a device by suitable means.

Installing to a directory image involves using -p switch to upip:

```
micropython -m upip install -p install_dir micropython-pystone_lowmem
```

After this command, the package content (and contents of every dependency packages) will be available in the `install_dir/` subdirectory. You would need to transfer contents of this directory (without the `install_dir/` prefix) to the device, at the suitable location, where it can be found by the Python `import` statement (see discussion of the `upip` installation path above).

5.6.5 Cross-installing packages with freezing

For the low-memory MicroPython ports, the process described in the previous section does not provide the most efficient resource usage, because the packages are installed in the source form, so need to be compiled to the bytecode on each import. This compilation requires RAM, and the resulting bytecode is also stored in RAM, reducing its amount available for storing application data. Moreover, the process above requires presence of the filesystem on a device, and the most resource-constrained devices may not even have it.

The bytecode freezing is a process which resolves all the issues mentioned above:

- The source code is pre-compiled into bytecode and store as such.
- The bytecode is stored in ROM, not RAM.
- Filesystem is not required for frozen packages.

Using frozen bytecode requires building the executable (firmware) for a given MicroPython port from the C source code. Consequently, the process is:

1. Follow the instructions for a particular port on setting up a toolchain and building the port. For example, for ESP8266 port, study instructions in `ports/esp8266/README.md` and follow them. Make sure you can build the port and deploy the resulting executable/firmware successfully before proceeding to the next steps.
2. Build MicroPython Unix port and make sure it is in your PATH and you can execute `micropython`.
3. Change to port’s directory (e.g. `ports/esp8266/` for ESP8266).
4. Run `make clean-frozen`. This step cleans up any previous modules which were installed for freezing (consequently, you need to skip this step to add additional modules, instead of starting from scratch).
5. Run `micropython -m upip install -p modules <packages>...` to install packages you want to freeze.
6. Run `make clean`.
7. Run `make`.

After this, you should have the executable/firmware with modules as the bytecode inside, which you can deploy the usual way.

Few notes:

1. Step 5 in the sequence above assumes that the distribution package is available from PyPI. If that is not the case, you would need to copy Python source files manually to `modules/` subdirectory of the port port directory. (Note that upip does not support installing from e.g. version control repositories).
2. The firmware for baremetal devices usually has size restrictions, so adding too many frozen modules may overflow it. Usually, you would get a linking error if this happens. However, in some cases, an image may be produced, which is not runnable on a device. Such cases are in general bugs, and should be reported and further investigated. If you face such a situation, as an initial step, you may want to decrease the amount of frozen modules included.

5.6.6 Creating distribution packages

Distribution packages for MicroPython are created in the same manner as for CPython or any other Python implementation, see references at the end of chapter. Setuptools (instead of distutils) should be used, because distutils do not support dependencies and other features. “Source distribution” (sdist) format is used for packaging. The post-processing discussed above, (and pre-processing discussed in the following section) is achieved by using custom sdist command for setuptools. Thus, packaging steps remain the same as for the standard setuptools, the user just needs to override sdist command implementation by passing the appropriate argument to setup() call:

```python
from setuptools import setup
import sdist_upip

setup(...,
    ...,
    cmdclass={'sdist': sdist_upip.sdist})
```

The sdist_upip.py module as referenced above can be found in `micropython-lib`: https://github.com/micropython/micropython-lib/blob/master/sdist_upip.py

5.6.7 Application resources

A complete application, besides the source code, oftentimes also consists of data files, e.g. web page templates, game images, etc. It’s clear how to deal with those when application is installed manually - you just put those data files in the filesystem at some location and use the normal file access functions.

The situation is different when deploying applications from packages - this is more advanced, streamlined and flexible way, but also requires more advanced approach to accessing data files. This approach is treating the data files as “resources”, and abstracting away access to them.

Python supports resource access using its “setuptools” library, using pkg_resources module. MicroPython, following its usual approach, implements subset of the functionality of that module, specifically pkg_resources.resource_stream(package, resource) function. The idea is that an application calls this function, passing a resource identifier, which is a relative path to data file within the specified package (usually top-level application package). It returns a stream object which can be used to access resource contents. Thus, the resource_stream() emulates interface of the standard open() function.

Implementation-wise, resource_stream() uses file operations underlyingly, if distribution package is instalt in the filesystem. However, it also supports functioning without the underlying filesystem, e.g. if the package is frozen as the bytecode. This however requires an extra intermediate step when packaging application - creation of “Python resource module”.

The idea of this module is to convert binary data to a Python bytes object, and put it into the dictionary, indexed by the resource name. This conversion is done automatically using overridden sdist command described in the previous section.

Let’s trace the complete process using the following example. Suppose your application has the following structure:
__main__.py and utils.py should access resources using the following calls:

```python
import pkg_resources

pkg_resources.resource_stream(__name__, "data/page.html")
pkg_resources.resource_stream(__name__, "data/image.png")
```

You can develop and debug using the MicroPython Unix port as usual. When time comes to make a distribution package out of it, just use overridden “sdist” command from sdist_upip.py module as described in the previous section.

This will create a Python resource module named R.py, based on the files declared in MANIFEST or MANIFEST.in files (any non-.py file will be considered a resource and added to R.py) - before proceeding with the normal packaging steps.

Prepared like this, your application will work both when deployed to filesystem and as frozen bytecode.

If you would like to debug R.py creation, you can run:

```bash
python3 setup.py sdist --manifest-only
```

Alternatively, you can use tools/mpy_bin2res.py script from the MicroPython distribution, in which you will need to pass paths to all resource files:

```bash
mpy_bin2res.py data/page.html data/image.png
```

## 5.6.8 References

MICROPYTHON DIFFERENCES FROM CPYTHON

The operations listed in this section produce conflicting results in MicroPython when compared to standard Python.

6.1 Syntax

Generated Mon 01 Oct 2018 04:55:44 UTC

6.1.1 Spaces

uPy requires spaces between literal numbers and keywords, CPy doesn’t

Sample code:

```python
try:
    print(eval('1and 0'))
except SyntaxError:
    print('Should have worked')
try:
    print(eval('1or 0'))
except SyntaxError:
    print('Should have worked')
try:
    print(eval('1if 1else 0'))
except SyntaxError:
    print('Should have worked')
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Should have worked</td>
</tr>
<tr>
<td>1</td>
<td>Should have worked</td>
</tr>
<tr>
<td>1</td>
<td>Should have worked</td>
</tr>
</tbody>
</table>

6.1.2 Unicode

Unicode name escapes are not implemented

Sample code:
print("\nLATIN SMALL LETTER A")

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>NotImplemented Error: unicode name escapes</td>
</tr>
</tbody>
</table>

## 6.2 Core Language

Generated Mon 01 Oct 2018 04:55:44 UTC

### 6.2.1 Classes

**Special method \_\_del\_\_ not implemented for user-defined classes**

Sample code:

```python
import gc

class Foo():
    def __del__(self):
        print('__del__')

f = Foo()
del f
gc.collect()
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>del</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Method Resolution Order (MRO) is not compliant with CPython**

**Cause:** Depth first non-exhaustive method resolution order

**Workaround:** Avoid complex class hierarchies with multiple inheritance and complex method overrides. Keep in mind that many languages don’t support multiple inheritance at all.

Sample code:

```python
class Foo:
    def __str__(self):
        return "Foo"

class C(tuple, Foo):
    pass
```
```python
t = C((1, 2, 3))
print(t)
```

<table>
<thead>
<tr>
<th>CPy output</th>
<th>uPy output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Foo</td>
<td>(1, 2, 3)</td>
</tr>
</tbody>
</table>

**When inheriting from multiple classes super() only calls one class**

**Cause:** See *Method Resolution Order (MRO) is not compliant with CPython*

**Workaround:** See *Method Resolution Order (MRO) is not compliant with CPython*

Sample code:

```python
class A:
    def __init__(self):
        print("A.__init__")

class B(A):
    def __init__(self):
        print("B.__init__")
        super().__init__()

class C(A):
    def __init__(self):
        print("C.__init__")
        super().__init__()

class D(B,C):
    def __init__(self):
        print("D.__init__")
        super().__init__()
D()
```

<table>
<thead>
<tr>
<th>CPy output</th>
<th>uPy output</th>
</tr>
</thead>
<tbody>
<tr>
<td>D.<strong>init</strong></td>
<td>D.<strong>init</strong></td>
</tr>
<tr>
<td>B.<strong>init</strong></td>
<td>B.<strong>init</strong></td>
</tr>
<tr>
<td>C.<strong>init</strong></td>
<td>A.<strong>init</strong></td>
</tr>
</tbody>
</table>

**Calling super() getter property in subclass will return a property object, not the value**

Sample code:

```python
class A:
    @property
    def p(self):
        return {"a":10}
```

6.2. Core Language
```python
class AA(A):
    @property
    def p(self):
        return super().p

a = AA()
print(a.p)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>{'a': 10}</td>
<td>&lt;property&gt;</td>
</tr>
</tbody>
</table>

### 6.2.2 Functions

**Error messages for methods may display unexpected argument counts**

**Cause:** MicroPython counts “self” as an argument.

**Workaround:** Interpret error messages with the information above in mind.

Sample code:

```python
try:
    [].append()
except Exception as e:
    print(e)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>append() takes exactly one argument (0 given)</td>
<td>function takes 2 positional arguments, but 1 were given</td>
</tr>
</tbody>
</table>

**User-defined attributes for functions are not supported**

**Cause:** MicroPython is highly optimized for memory usage.

**Workaround:** Use external dictionary, e.g. `FUNC_X[f] = 0`.

Sample code:

```python
def f():
    pass

f.x = 0
print(f.x)
```
6.2.3 Generator

Context manager __exit__() not called in a generator which does not run to completion

Sample code:

```python
class foo(object):
    def __enter__(self):
        print('Enter')
    def __exit__(self, *args):
        print('Exit')

def bar(x):
    with foo():
        while True:
            x += 1
            yield x

def func():
    g = bar(0)
    for _ in range(3):
        print(next(g))

func()
```

6.2.4 Runtime

Local variables aren’t included in locals() result

**Cause:** MicroPython doesn’t maintain symbolic local environment, it is optimized to an array of slots. Thus, local variables can’t be accessed by a name.

Sample code:

```python
def test():
    val = 2
```
```python
print(locals())
test()
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| ('val': 2)  | {'test': <function test at 0xf7b7b180>,
   '__name__': '__main__', '__file__': '<stdin>'} |

### Code running in eval() function doesn’t have access to local variables

**Cause:** MicroPython doesn’t maintain symbolic local environment, it is optimized to an array of slots. Thus, local variables can’t be accessed by a name. Effectively, `eval(expr)` in MicroPython is equivalent to `eval(expr, globals(), globals())`.

Sample code:

```python
val = 1
def test():
    val = 2
    print(val)
    eval("print(val)")
test()
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

### 6.2.5 import

**__path__ attribute of a package has a different type (single string instead of list of strings) in MicroPython**

**Cause:** MicroPython does’t support namespace packages split across filesystem. Beyond that, MicroPython’s import system is highly optimized for minimal memory usage.

**Workaround:** Details of import handling is inherently implementation dependent. Don’t rely on such details in portable applications.

Sample code:

```python
import modules
print(modules.__path__)
```
Failed to load modules are still registered as loaded

_Cause:_ To make module handling more efficient, it’s not wrapped with exception handling.

_Workaround:_ Test modules before production use; during development, use `del sys.modules["name"],` or just soft or hard reset the board.

_Sample code:_

```python
import sys

try:
    from modules import foo
except NameError as e:
    print(e)

try:
    from modules import foo
    print('Should not get here')
except NameError as e:
    print(e)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>['/home/micropython/micropython-docs/ → tests/cpydiff/modules']</td>
<td>../tests/cpydiff//modules</td>
</tr>
</tbody>
</table>
6.3 Builtin Types

Generated Mon 01 Oct 2018 04:55:44 UTC

6.3.1 Exception

Exception chaining not implemented

Sample code:

```python
try:
    raise TypeError
except TypeError:
    raise ValueError
```

User-defined attributes for built-in exceptions are not supported

**Cause:** MicroPython is highly optimized for memory usage.

**Workaround:** Use user-defined exception subclasses.

Sample code:

```python
e = Exception()
e.x = 0
print(e.x)
```
Exception in while loop condition may have unexpected line number

**Cause:** Condition checks are optimized to happen at the end of loop body, and that line number is reported.

Sample code:

```python
l = ["-foo", "-bar"]
i = 0
while l[i][0] == ":
    print("iter")
i += 1
```

Exception.__init__ method does not exist.

**Cause:** Subclassing native classes is not fully supported in MicroPython.

**Workaround:** Call using `super()` instead:

```python
class A(Exception):
    def __init__(self):
        super().__init__()
```

Sample code:

```python
class A(Exception):
    def __init__(self):
        Exception.__init__(self)
a = A()
```
6.3.2 bytearray

Array slice assignment with unsupported RHS

Sample code:

```python
b = bytearray(4)
b[0:1] = [1, 2]
print(b)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traceback (most recent call last):</td>
<td>Traceback (most recent call last):</td>
</tr>
<tr>
<td>File &quot;&lt;stdin&gt;&quot;, line 8, in &lt;module&gt;</td>
<td>File &quot;&lt;stdin&gt;&quot;, line 7, in &lt;module&gt;</td>
</tr>
<tr>
<td>NotImplementedError: array/bytes required on right side</td>
<td>NotImplementedError: keyword argument(s) not yet implemented - use normal args instead</td>
</tr>
</tbody>
</table>

6.3.3 bytes

bytes() with keywords not implemented

**Workaround:** Pass the encoding as a positional paramter, e.g. `print(bytes('abc', 'utf-8'))`

Sample code:

```python
print(bytes('abc', encoding='utf8'))
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>b'abc'</td>
<td>Traceback (most recent call last):</td>
</tr>
<tr>
<td></td>
<td>File &quot;&lt;stdin&gt;&quot;, line 7, in &lt;module&gt;</td>
</tr>
<tr>
<td></td>
<td>NotImplementedError: keyword argument(s) not yet implemented - use normal args instead</td>
</tr>
</tbody>
</table>

**Bytes subscription with step != 1 not implemented**

**Cause:** MicroPython is highly optimized for memory usage.

**Workaround:** Use explicit loop for this very rare operation.
Sample code:

```python
print(b'123'[0:3:2])
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| b'13'       | Traceback (most recent call last):  
|             | File "<stdin>", line 7, in <module>  
|             | NotImplementedError: only slices with step=1 (aka None) are supported |

### 6.3.4 float

uPy and CPython outputs formats may differ

Sample code:

```python
print('%.1g' % -9.9)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>-le+01</td>
<td>-10</td>
</tr>
</tbody>
</table>

### 6.3.5 int

No int conversion for int-derived types available

Sample code:

```python
class A(int):
    __add__ = lambda self, other: A(int(self) + other)

a = A(42)
print(a+a)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| 84          | Traceback (most recent call last):  
|             | File "<stdin>", line 11, in <module>  
|             | File "<stdin>", line 8, in <lambda>  
|             | TypeError: can't convert A to int |

### 6.3.6 list
List delete with step $\neq 1$ not implemented

**Workaround:** Use explicit loop for this rare operation.

Sample code:

```python
l = [1, 2, 3, 4]
del l[0:4:2]
print(l)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| [2, 4]      | Traceback (most recent call last):  
|             | File "stdin", line 8, in <module>  
|             | NotImplemented: |

List slice-store with non-iterable on RHS is not implemented

**Cause:** RHS is restricted to be a tuple or list

**Workaround:** Use `list(<iter>)` on RHS to convert the iterable to a list

Sample code:

```python
l = [10, 20]
l[0:1] = range(4)
print(l)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| [0, 1, 2, 3, 20] | Traceback (most recent call last):  
|                | File "stdin", line 8, in <module>  
|                | TypeError: object 'range' is not a tuple  
|                | or list |

List store with step $\neq 1$ not implemented

**Workaround:** Use explicit loop for this rare operation.

Sample code:

```python
l = [1, 2, 3, 4]
l[0:4:2] = [5, 6]
print(l)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| [5, 2, 6, 4] | Traceback (most recent call last):  
|             | File "stdin", line 8, in <module>  
|             | NotImplemented: |
6.3.7 str

Start/end indices such as str.endswith(s, start) not implemented

Sample code:

```
print('abc'.endswith('c', 1))
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>Traceback (most recent call last): File &quot;&lt;stdin&gt;&quot;, line 7, in &lt;module&gt; NotImplemented Error: start/end indices</td>
</tr>
</tbody>
</table>

Attributes/subscr not implemented

Sample code:

```
print('a[0]'.format(a=[1, 2]))
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Traceback (most recent call last): File &quot;&lt;stdin&gt;&quot;, line 7, in &lt;module&gt; NotImplemented Error: attributes not supported yet</td>
</tr>
</tbody>
</table>

str(...) with keywords not implemented

**Workaround:** Input the encoding format directly. e.g. `print(bytes('abc', 'utf-8'))`

Sample code:

```
print(str(b'abc', encoding='utf8'))
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>abc</td>
<td>Traceback (most recent call last): File &quot;&lt;stdin&gt;&quot;, line 7, in &lt;module&gt; NotImplemented Error: keyword argument(s) not yet implemented - use normal args instead</td>
</tr>
</tbody>
</table>

str.ljust() and str.rjust() not implemented

**Cause:** MicroPython is highly optimized for memory usage. Easy workarounds available.

**Workaround:** Instead of `s.ljust(10)` use `"%-10s" % s`, instead of `s.rjust(10)` use `"% 10s" % s`. Alternatively, `"{:<10}".format(s)` or `"{:>10}".format(s).`
Sample code:

```python
print('abc'.ljust(10))
```

<table>
<thead>
<tr>
<th>CPy output</th>
<th>uPy output</th>
</tr>
</thead>
</table>
| abc        | Traceback (most recent call last):
  File "<stdin>", line 7, in <module>
  AttributeError: 'str' object has no attribute 'ljust' |

**None as first argument for rsplit such as str.rsplit(None, n) not implemented**

Sample code:

```python
print('a a a'.rsplit(None, 1))
```

<table>
<thead>
<tr>
<th>CPy output</th>
<th>uPy output</th>
</tr>
</thead>
</table>
| ['a a', 'a'] | Traceback (most recent call last):
  File "<stdin>", line 7, in <module>
  NotImplementedError: rsplit (None, n) |

**Instance of a subclass of str cannot be compared for equality with an instance of a str**

Sample code:

```python
class S(str):
    pass
s = S('hello')
print(s == 'hello')
```

<table>
<thead>
<tr>
<th>CPy output</th>
<th>uPy output</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>False</td>
</tr>
</tbody>
</table>

**Subscript with step != 1 is not yet implemented**

Sample code:

```python
print('abcdefghi'[0:9:2])
```
6.3.8 tuple

Tuple load with step != 1 not implemented

Sample code:

```python
print((1, 2, 3, 4)[0:4:2])
```

6.4 Modules

Generated Mon 01 Oct 2018 04:55:44 UTC

6.4.1 array

Looking for integer not implemented

Sample code:

```python
import array
print(1 in array.array('B', b'12'))
```

Array deletion not implemented

Sample code:
import array
a = array.array('b', (1, 2, 3))
del a[1]
print(a)

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| array('b', [1, 3])     | Traceback (most recent call last):
                        |   File "<stdin>", line 9, in <module>
                        |   TypeError: 'array' object does not support item deletion |

Subscript with step != 1 is not yet implemented

Sample code:

import array
a = array.array('b', (1, 2, 3))
print(a[3:2:2])

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| array('b')             | Traceback (most recent call last):
                        |   File "<stdin>", line 9, in <module>
                        |   NotImplementedError: only slices with step=1 (aka None) are supported |

6.4.2 builtins

Second argument to next() is not implemented

**Cause:** MicroPython is optimised for code space.

**Workaround:** Instead of `val = next(it, deflt)` use:

```
try:
    val = next(it)
except StopIteration:
    val = deflt
```

Sample code:

```
print(next(iter(range(0)), 42))
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| 42                     | Traceback (most recent call last):
                        |   File "<stdin>", line 12, in <module>
                        |   TypeError: function takes 1 positional arguments but 2 were given |
6.4.3 deque

Deque not implemented

**Workaround:** Use regular lists. micropython-lib has implementation of collections.deque.

Sample code:

```python
import collections
D = collections.deque()
print(D)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
</table>
| deque([])         | Traceback (most recent call last):
|                   | File "<stdin>"", line 8, in <module>
|                   | TypeError: function missing 2 required, positional arguments |

6.4.4 json

JSON module does not throw exception when object is not serialisable

Sample code:

```python
import json
a = bytes(x for x in range(256))
try:
    z = json.dumps(a)
    x = json.loads(z)
    print('Should not get here')
except TypeError:
    print('TypeError')
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>TypeError</td>
<td>Should not get here</td>
</tr>
</tbody>
</table>

6.4.5 struct

Struct pack with too few args, not checked by uPy

Sample code:

```python
import struct
try:
    print(struct.pack('bb', 1))
    print('Should not get here')
except:
    print('struct.error')
```
Struct pack with too many args, not checked by uPy

Sample code:

```python
import struct
try:
    print(struct.pack('bb', 1, 2, 3))
    print('Should not get here')
except:
    print('struct.error')
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>struct.error</td>
<td>b'\x01\x00'</td>
</tr>
<tr>
<td>Should not get here</td>
<td>Should not get here</td>
</tr>
</tbody>
</table>

6.4.6 sys

Overriding sys.stdin, sys.stdout and sys.stderr not possible

Cause: They are stored in read-only memory.

Sample code:

```python
import sys
sys.stdin = None
print(sys.stdin)
```

<table>
<thead>
<tr>
<th>CPy output:</th>
<th>uPy output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>struct.error</td>
<td>b'\x01\x02'</td>
</tr>
<tr>
<td>Should not get here</td>
<td>Should not get here</td>
</tr>
</tbody>
</table>

| None                         | Traceback (most recent call last):
|------------------------------| File "<stdin>", line 8, in <module>
|                              | AttributeError: 'module' object has no attribute 'stdin' |
